Local and Regional Anæsthesia. By CARROLL W. ALLEN, M.D. Second edition, reset. London and Philadelphia: W. B. Saunders Company. 1918. Pp. 674. 28*s.*

SINCE the appearance of the first edition of this book three years ago the scope of local analgesia has widened considerably. Dr. Allen's work remains, however, one of the most complete accounts in the English language both of the technique and of the physiological explanations of analgesia by local injection. The chapter on Nerves and their Sensations, especially Pain, may be read with profit and interest even by those not immediately concerned with the use of local anæsthetics. The author regards the application of this method to the operations for removal of the prostate as one of the most important recent developments of local anæsthesia, and there can be no doubt that many of the subjects of prostatectomy are just those for whom general anæsthesia, however skilfully conducted, affords more than the usual risk. The pages dealing with this operation are worthy of careful study by all surgeons; the author seems in general to prefer operation in two stages; local analgesia makes a heavy call upon the time, patience, and skill of the surgeon, but the results here recorded justify such an outlay. The best medium for anæsthetic solutions is found by Dr. Allen to be a 0·4 per cent. solution of sodium chloride, and he regards novocaine as the anæsthetic which hitherto most nearly meets all the requirements demanded of a perfect local agent. He writes that after an experience embracing the entire field of surgery he has failed to note a single case in which this agent has produced any unpleasant local or constitutional action.

The pleasure of perusing this valuable book is marred by a certain carelessness of diction in which nouns fail to agree in number with the verbs dependent on them, and while it is priggish to suggest that infinitives should never be split, the proper order of words could have frequently been preserved without loss of clearness. None the less, text and illustration are highly commendable work.

Diseases of the Skin. By MILTON H. HARTZELL, Professor of Dermatology at the University of Pennsylvania. With 51 coloured plates and 242 illustrations. London and Philadelphia: Lippincott Company. Pp. 753. 30*s.* net.

IN this country text-books dealing with dermatology are few, and the majority of them are of considerably smaller size than many which appear in America. Professor Hartzell in this regard follows the example of his countrymen, but there is not a page that could be spared. The matter is concentrated and accurate; there is throughout evidence of that thorough knowledge which enables an author to achieve compression without lack of clearness. Treatment is carefully considered, and practical as to detail. The illustrations are well selected and life-like, up to the modern high standard. The consideration of X ray treatment in dermatology is more detailed than we remember to have seen in other American text-books, and the intimate acquaintance with European literature is another high recommendation to a volume appearing in Britain.

Professor Hartzell states in his preface that his experience in general medicine has enabled him to survey the subject of dermatology from the standpoint of the general practitioner as well as that of the specialist. Reference to the paragraphs on etiology and treatment throughout the book shows that this claim is well founded. This is certainly a much needed method of approaching certain diseases, such as eczema, which are dependent upon and vary with the general health. Professor Hartzell considers carefully in this respect the subject of protein hypersensitiveness. Every dermatologist has met with instances of eczema, alternating with asthma, which yield only to a careful dietetic régime. Recently treatment of asthma by injections of foreign proteins has yielded promise of success, and it is therefore of interest to learn that cutaneous tests with various foodstuffs have been carried out in order to ascertain whether the eczematous patient exhibits anaphylactic reaction to selected substances. Psoriasis is another common malady affected by the general health, but this author has found no royal road to its permanent cure

The volume should be a favourite with the advanced student because of the practical nature of its teaching.

Treatise on Applied Analytical Chemistry. By Professor VITTORIO VILLAVECCHIA. Translated by THOMAS H. POPE, B.Sc., A.C.G.I., F.I.C. London: J. and A. Churchill. 1918. Vol. I. Pp. 475. 21*s.* net. Vol. II. Pp. 536. 25*s.* net.

Professor Vittorio Villavecchia's two volumes cover a wide field; the methods and standards described bear witness to his experience in every branch of analytical practice, derived, no doubt, from his directorship of the chemical laboratories of the Italian Customs. The first volume deals with the analysis of potable waters, chemical products, fertilisers, cement materials, metals and alloys, fuels, tar and its derivatives, mineral oils and fatty substances, and the industrial products derived therefrom. The second volume includes chapters on the analysis of flesh foods, milk products, flour and starches, sugars and saccharine products, beer, wine, spirits and liqueurs, essential oils, turpentine, varnishes, rubber, tanning materials, leather, colouring matters, and textile fibres and fabrics. The general plan employed in the presentation of the many analytical methods involved will be much appreciated by the analyst. First a brief statement is given of the different cases and the problems which arise, as well as of the investigations and determinations to be made to solve them. Then follows a detailed description of the methods to be carried out. Then, most valuable of all, the criteria and standards are given by the aid of which the industrial, commercial, or hygienic value of the product may be deduced from the analytical data obtained. Finally, tables are given containing examples of the analytical results relating to the ordinary commercial qualities of the product. All this is excellent, particularly when we find that care has been taken to select those up-to-date methods which have been shown to be trustworthy and convenient. The book is a standard work of reference on the whole subject, and an excellent guide on analytical detail.

Reports and Analytical Records FROM THE LANCET LABORATORY.

(1) AMBRINE CANDLES; (2) MORUBILINE; (3) NÉVROS THÉNINE (FREYSSINGE); AND (4) QUINÉINE.

(ANGLO-FRENCH DRUG CO., LTD., GAMAGE BUILDING, HOLBORN, LONDON, E.C. 1.)

(1) THE ambrine candle provides a simple and safe method of applying melted wax to the skin in the treatment of burns, wounds, and abrasions generally. It dispenses with the use of an outfit of accessories hitherto employed, including sterilising apparatus, though the skilled dresser would prefer to continue the more elaborate method when the surface to be treated is extensive. In the ambrine candle, when the wick is lighted, the melted wax is sufficiently fluid to pour on a burn or wound, and yet is not so hot as to cause suffering, and a candle can be used, with common precautions, in the household and workshop readily and conveniently. We received two specimens: (*a*) a plain single stick, and (*b*) a tricandle (three candles waxed together lengthwise, forming three circles in a triangle).

(2) Morubiline is a dark brown syrupy fluid which is described as the extract of the fresh liver of the cod, to which has been added certain preparations containing phosphorus, iodine, sulpho-guaiacolate of potassium, and methyl arsenate of sodium. We confirmed the presence of these constituents and also found that an ethereal extract gave a purple colouration with sulphuric acid and glucose—the Pettenkofer reaction for biliary acids. In view of recent researches on the part played by accessory factors in animal fats, the theory has been revived that the value of cod liver oil in nutrition may be connected with the presence of such substances.

(3) "Névrosthénine" is a concentrated solution of the glycerophosphates of magnesium, sodium, and potassium, the inclusion of common calcium salt being omitted on the ground that it favours sclerosis.

(4) Quinéine is described as an integral extract of the active principles of cinchona bark, the inert products being excluded. The therapeutic indications are the same as those of quinine, but a claim is made for special efficiency ascribed to the improved method of preparation adopted.

EVATMINE.

(BRITISH ORGANOTHERAPY CO., LTD., 22, GOLDEN-SQUARE, REGENT-STREET, LONDON, W.1.)

This combination in the treatment of asthma is the outcome of clinical experience in France, and the formula is as follows: Pituitary extract (posterior lobe), $\frac{1}{3}$ gr.; adrenin solution (1:1000), 8 minims; physiological salt solution, 8 minims. The preparation is contained in sterilised ampoules of 1 c.cm., with the above quantities of organo-therapeutic constituents. The administration of adrenal extract has long been known to give relief in the paroxysms of asthma, but some interesting evidence is quoted that in combining this hæmostatic principle with pituitary extract the results are more satisfactory than when adrenin alone is used, as not only is the paroxysm rapidly cut short, but the intervals of attack are markedly increased when pituitary extract is simultaneously given. The two are combined in "evatmine."

SOTOL.

(WESTERN DENTAL MANUFACTURING CO. (1914), LTD., 73, 75, AND 79, QUEEN'S-ROAD, BRISTOL.)

Sotol tablets are not inaptly described as "mouth, nose, and throat baths," for in water they produce a pleasant, briskly effervescing solution containing well-known antiseptics suitable for cleansing the mucosa indicated. The antiseptics consist of menthol, thymol, and certain aromatic oils with an alkaline basis, which renders them agreeable to use and mildly detergent. The effervescence serves to circulate the antiseptics uniformly through the fluid, whilst giving it a pleasant, somewhat piquant taste. There is a feeling that the mouth and nasal passages are clean after the use of "sotol" solution and a healthy condition established. The introduction of an effervescing wash for the purpose is, so far as we know, novel.

FERMENTOSE.

(A. BREZET AND CO., 145, WOOL EXCHANGE, LONDON, E.C.2.)

In French clinics "la fermentose" has been employed in diseases arising out of disorders of nutrition, and notably neurasthenia. Its action is said to be that of a constructive metabolic agent restoring healthy functional activity in the gastro-intestinal tract. Its pharmacology is based on the presence of digestive ferments and an oxydase in the form of a metallic catalyst or activator. Fermentose occurs as a pale brownish powder, which is enclosed in cachets for administration. Two of these are prescribed daily, one with the mid-day and the other with the evening meal. We confirmed its hydrolytic activity *in vitro* and found a fairly large proportion of alkaline bi-carbonate present. We found also on suitable treatment the presence of metal, but, of course, in small quantity. The employment of a metallic "ferment" with well-known enzymes in disorders of metabolism is of interest, and suggests further clinical trials being made.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS TO THE SECOND APPEAL.

THE following subscriptions have been received up to Monday last, Nov. 11th:—

	£	*s.*	*d.*
Mr. W. H. Quarrell ...	1	0	0
Mr. E. Spencer Evans (monthly)	0	10	0
North of England Branch B.M.A (per Dr. J. Don, Hon. Sec.)—			
Dr. H. P. Bennett ...	1	1	0
Dr. C. R. Sutherland	1	1	0
Dr. A. Bruce Low ...	1	1	0
Dr. D. Galloway... ...	1	1	0
Dr. A. MacKay	1	1	0
Dr. James Hamilton	1	1	0
Dr. S. J. Brookfield Fox	2	2	0
Dr. Alex. Brown... ...	1	1	0
Dr. James Hern	1	1	0
Dr. J. Lawrence... ...	1	1	0
Dr. T. M. Kimpster ...	2	2	0
Hampshire Pharmacists Association (per Mr. C. H. Baker)	50	0	0
Dr. H. F. Staunton ...	1	1	0
The Grocers' Company	50	0	0

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 16, 1918.

Peace.

THE cessation of hostilities has let loose a flood of feeling which has long been unnaturally restrained. The traditional procession in London on Saturday to initiate the new Lord Mayor in office was a striking military ceremony carried through with dignity and order. The same streets re-echoed on Monday to the unrestrained cries of a nation free once more to rejoice, and if the celebrations of peace in the capital seem to have been particularly flamboyant this was probably due to the presence in London of such large numbers of American and Colonial troops. In his Guildhall speech the Prime Minister, with instinctive response to the emotions of the nation, characterised the occasion as not an hour for speeches but for thankfulness—thankfulness for the end of a struggle which is going to lift humanity to a higher plane of existence for future ages. He appealed to his hearers, as they had by their unity achieved victory in war, so they should unite in peace to lift up their country by common effort to a position such as it never yet held in its history. Here medicine will see a particular appeal to herself. Medicine has achieved undreamed-of things by unity and organisation during the last four years. The chapter of the Four Years' War, which is now closed, may well be the beginning of a new era of physical health.

The Ministry of Health Bill.

ON Thursday evening last week Dr. ADDISON, the Minister of Reconstruction, introduced in the House of Commons the Ministry of Health Bill. Many of our readers may not have been able by this time to see the text of the measure, but they will have read such a large number of abstracts of it and commentaries upon it that we may assume their familiarity with its general design, as read for the first time. They are probably satisfied with much that it is proposed to do, but it is none the less necessary that the extensive scope and possibilities of the Bill should be closely realised, although its future is seriously compromised. The Bill will not be proceeded with this session, but whether this Bill or some other be in question, a Ministry of Health can only discharge its functions properly towards the public if it conducts its affairs with the coöperation of enlightened medicine. The Bill combines under one State Department all the existing responsibilities of the Local Government Board as far as health is concerned, and all the functions of the National Insurance Commissions for England and Wales. There will also be included the duties of the Board of Education in respect of the health of expectant and nursing mothers and children under five years. The Bill proposes to bring into the same Department the duties of the Home Office in regard to the protection of infant life under the Children Act, 1908, and those of the Privy Council, as administered through the Central Midwives Board, in regard to the midwifery practice of the country. That is the combining scheme of the Bill in respect of existing activities, but the Bill also proposes to give the new Ministry power to bring in other considerable health duties, and all these can be directed under intelligent guidance towards improvement in national health and its steady maintenance upon the higher planes. Thus medical inspection of school children and young persons, which now appertains to the Board of Education, and the duties of the Home Office in regard to lunacy and mental deficiency, if and when possible, may be included in the work of the new Department, while the Ministry of Pensions will also surrender to it the care of the sick soldier. When each additional burden can be best borne we may expect to see the process of solidification go on. A large programme, but one whose object is common; in which, therefore, common wisdom at the centre can well be infused into the different procedures at the periphery. Consultative Councils will be instituted to advise the Ministry in the proper directions, and the functions of these bodies have yet to be announced.

Such in brief are the chief provisions of the Bill instituting the Ministry of Health, and in introducing it Dr. ADDISON claimed that the measure was the outcome of general agreement, save in details, the agreement having been arrived at after consultations with many local authorities, medical men, and representatives of the Approved Societies under the National Insurance Act. We may be certain that the consolidation of existing State energies was viewed with approval by all who were asked, as it will be by others. The step is one which has been demanded in our columns and in those of the *British Medical Journal* for a long time, since those whose business it is to follow public administration in relation to medical affairs have known that the overlapping under the existing conditions was a perpetual impediment to progress. None the less, the Board of Education could not resign without real regret its functions of medical inspection and treatment of school children, and we have every reason to think that no such step will yet be taken. Certain difficulties which lie ahead can be focussed around questions of Poor-law. The present position of Poor-law administration does not lend itself to an easy transfer of responsibilities to any new central authority. The Boards of Guardians, the responsible authorities under the Poor-law, owe allegiance to the Local Government Board in other directions besides those which lead directly towards the maintenance and progress of health, though in all these directions the health of the people may be really concerned. Still, its medical duties form a very large part of the Poor-law. A recent Committee, presided over by Sir DONALD MCLEAN, Deputy Chairman of Ways and Means, in considering the transfer of the functions of the Poor-law authorities in England

and Wales, recommended that the services relating to the care and treatment of the sick and infirm should no longer be administered as part of the Poor-law but should all be made a part of the general health service of the country. The Government was stated by Dr. ADDISON—and the point is one of enormous importance—to regard the carrying out of this recommendation as a matter of urgency, and effect will be given to it by the inclusion of Poor-law medical administration in the work of the new Ministry as soon as the general policy for the transfer of the remaining functions of the Poor-law authorities to other hands has been settled, but some time must elapse before this can be definitely accomplished. The whole problem here presents considerable difficulties, but the Bill need not be delayed in other respects until what is commonly called "the break-up of the Poor-law" is accomplished. With regard to Scotland, the Bill brings together in practically the same way as in England the different State activities of medicine in that country, and institutes a Board of Health for the country which will be under the direction of the Secretary for Scotland. The position of Ireland for the present will be that the National Insurance will remain under the same direction as the Local Government Board of Ireland. The resolution into national components of insurance administration places the Medical Research Committee without the scope of the Bill, and with magnificent prospects before it.

The measure is an administrative one, and its main results will emerge not from the fusion of overlapping energies, and, at first at any rate, not from the development of constructive work made possible where system reigns in place of disorder. The results which will be appreciated practically will follow upon the part played by the Consultative Councils. If the functions of these Councils are well defined, if their advice is accepted as being in great measure authoritative—which means if their constitution is scrupulously considered—and if the public is kept duly informed of the reasons which determine State action on medical grounds, there resides in these Councils a power for good of incommensurable strength. The people want to be healthy. It is not apathy which makes sections of our population blind to their insanitary plight, or which keeps localities satisfied when their death-rates and infantile mortality are scandalous. This calm does not come from apathy—behind the supineness is ignorance. It is usual to say here that the housing of the poor and the industrial wages being what they are, salvation cannot be obtained by sanitary administration or institutional or domestic medicine. Granted to a certain point; but if the people knew what sanitary and medical science could do for them, a popular war would be waged against dirt and disease as successful as that which a popular war has waged against German militarism. And the end would be similar. The Ministry of Health Bill should constitute a great alliance between authorities for the putting down of insanitation and erecting the standard of personal hygiene; the authorities must secure the best advisers, when a well-instructed people will see that the counsels of these advisers are followed.

The Sexual Complement.

IN certain insects, such as *Bombyx mori*, parthenogenesis, or the complete evolution of the adult form from an unfertilised ovum, is known occasionally to occur; and this is a phenomenon probably capable of some biochemical explanation not yet understood. Among some of the lower invertebrates, such as *Ciona intestinalis* and *distomum*, the individual is all-sufficient unto itself in regard to the reproductive functions: each is male and female, not only structurally but also functionally. In Nudibranchs and Vermes it is usual to find only structural hermaphroditism, as it is called—that is to say, each creature has functional male and female gonads, but cannot fertilise itself. From this stage of evolution we find an increasing divergence in the sexes; but a divergence only, for the separation is never complete; even in the human subject there are structural, and probably functional, attributes of the opposite sex. In the lower vertebrates, such as the fishes and some amphibians, the ova are expelled by the females from their oviducts to the exterior, and are fertilised by the spermatozoa which the male pours over them. In certain of the amphibians, such as *Salamandra maculosa*, we see the first attempt at copulation with the entry of the spermatozoa into the female channels and the fertilisation of the ova within the oviducts—a constant physiological performance in all the higher animals. The phylogenetic importance of copulation and viviparity, as seen in the mammals above the monotremes which are oviparous, has been the subject both of serious study and of speculation. Many interesting differences in the manner in which the sexual act is accomplished, and in the immediate results thereof, are to be noted. It is impossible here to enter into all the details, each of which is of some morphological or physiological importance, but attention may be directed to two phenomena which have, perhaps, some special bearing on the subject under discussion. First, in rabbits, and probably in other rodents, copulation mechanically causes dehiscence of the ripe Graafian follicles in the ovaries; second, the inseparability of the bitch from the dog for some minutes after the semen has been ejaculated allows time for the spermatozoa to enter the uterus. Viviparity, in all the stages of completeness of placental fusion and chemical interchange between the mother and fœtus, can be traced from the marsupials to Man. It is almost certain that the evolution of the processes of reproduction has been far more concerned with the requirements of the offspring than with the welfare of the forbears: the parents, as such, are by their individual lives serving posterity, and to such an extent does this obtain in some of the lower creatures that death closely follows reproductive consummation. There can be little doubt, however, that in the later phases of evolution Nature offers many compensations and rewards to those who fulfil the reproductive destiny that is theirs.

In an article in THE LANCET of Nov. 9th Sir ARBUTHNOT LANE discusses the sexual and reproductive functions from the point of view of the health of the progenitor, rather than of the claims of posterity. Yet it is obvious, of course, that in a perfect scheme of sexual opportunity the generations to come need not suffer; indeed, with sexual prohibitions as well as sexual facilities considerable benefit might accrue. Sir ARBUTHNOT LANE, however, is chiefly concerned with the health of the women of our

civilisation. He draws attention to his own valuable work on the secondary structural characteristics of Woman, and he refers to well-known facts concerning the thyroid gland and its relation to the genital functions in the female. Other evidence, too, concerning the correlation of most, if not of all, of the internal secretions in their influence on the sexual characteristics and functions might well be adduced; but in the present day it is not necessary to labour the question of sex-differences—physical, physiological, and psychological—for they may safely be accepted. Sir ARBUTHNOT LANE raises interesting physiological considerations in regard to the sexual relations between Man and Woman. His statements indicate that intercourse and gestation are beneficial to Woman. This is certainly true, though the measure of the truth is probably proportionate to the exact differentiation of the individual into male and female. All medical men know how different in health and outlook may be the unloved woman from the happy wife and mother; yet many can recall instances in which celibacy has left *apparently* unaffected both the physiology and psychology. Yet most normal, healthy women become more womanly, more composed and happy, and their vital organs more vigorous as the result of gestation and lactation. But this effect will take place in proportion to the distinct sexual divergence already mentioned, which is present in the individual.

But apart from conception and its results, is there any evidence to show that sexual intercourse is beneficial to Woman? Sir ARBUTHNOT LANE says that there is, and we are inclined to agree with him, but not on the ground stated—namely, that the prostatic secretion is absorbed by the female and is "far-reaching and active in its results." With regard to the male, the prostate is said to be an organ of internal secretion that acts as a "powerful stimulant." With this statement, too, we find it difficult to agree. The glands in the prostate are developed from the epithelium of the urogenital sinus in close relationship with the urethra. In the female the homologue of the prostatic glands is to be found in the para-urethral glands. Castration produces atrophy in the prostate, but recent observations—experimental and clinical—indicate that prostatectomy does not lead to retrogressive changes in the testes, as originally stated by SERRALACH and PARÈS. Further, it is unlikely on phylogenetic grounds that the prostate is an organ of internal secretion, for even in the lowest mammals—a late stage of evolution—there is no prostate, nor are there vesiculæ seminales; indeed, until the urethral canal, through which both urine and semen are voided, is formed, this gland is not developed. It is probable that the prostate subserves only the functions and requirements of the spermatozoa—that is to say, the external secretion keeps active the male sex-cells, and by the production of a ferment known as "vesiculase" causes temporary coagulation of the fluid from the vesiculæ seminales after ejaculation, a condition that prevents the easy escape of the semen from the vagina. The absorbent properties of the vagina have not been sufficiently studied, but in view of its structure these cannot be great. The benefits, then, that a woman derives from sexual intercourse, apart from the advantages of conception, are mechanical, sensory, and psychological, and these, it is true, may greatly affect her normality and well-being. Hence the importance of what we may call the "sexual complement," which, as Sir ARBUTHNOT LANE indicates, is frequently not available in the present state of civilisation.

Annotations.

"Ne quid nimis."

THE MENTALITY OF THE WAR PRISONER.

PRISONERS' camps in all parts of Europe are being broken up, and the early return of our own prisoners of war and of civilian internés from enemy countries is expected. Much has been written, but little is definitely known, about their mental well-being, and we welcome a little pamphlet[1] of 50 pages by Dr. A. L. Vischer, of Basle, devoted to the study of the psychology of prisoners of war, and especially to what was first called the "barbed-wire disease" in an agreement for exchange made between this country and Germany in July, 1917. Dr. Vischer is a surgeon in Basle, and does not claim for himself special experience in mental affections, but he has himself spent much time in various prisoners' camps in different countries (he was attached to the Swiss Consulate in London), has conversed with hundreds of prisoners, and learned to know many of them. His experience is therefore first-hand, and he claims that it is important owing to the fact that 4 or 5 million men have been kept in confinement in enemy countries, and that many of them will return with impaired mentality to their homes. Dr. Vischer is well read in his subject and accepts Dr. F. W. Mott's dictum (THE LANCET, Jan. 26th, 1918) that hysteria and severe neurasthenia are seldom seen in prisoners' camps; but he draws a picture of a mentality characteristic of prisoners of war, to which the majority fall victim within two or three months and from which few escape completely. The factors in its causation he considers to be partly the monotonous and scanty food-supply, the absence of fresh air, the circumstances of their incarceration, the loss of personal freedom, and the loneliness; summing up in one sentence the three basal factors as follows—loss of liberty for an unknown period in close company with many others. The result is a continual longing with entire inability to perform. The factor of loneliness in the midst of company he illustrates from writings emanating from various camps. A little poem entitled "Lagereinsamkeit," from Knockaloe, begins with the stanza—

> Kein Plätzchen in der Hütte,
> Kein Fuss breit Platz im Freien,
> Wo du nur auf Sekunden
> Mal könntest einsam sein—

which may be compared with a passage from Gaston Riou's "Journal d'un Simple Soldat," which runs:—

> "..... vivre entre hommes, rien qu'entre hommes, tous les jours, toutes les nuits, cœur à cœur, bec à bec, griffe à griffe, sans activité, sans solitude, sans la compagnie de femmes—c'est autre solitude,—oui, c'est cela le purgatoire!"

And in the midst of this loneliness "the barbed wire draws itself like a red thread" through his whole world of thoughts. Not only so, but it impels him to resistance. The prisoner finds himself obliged to kick against the pricks. He is always on the defensive, and begins to complain not only of the management of the camp, but also of his friends and relatives, and this not only in word but in writing. The camp magazines of all countries

[1] Die Stacheldraht-Krankheit: Beiträge zur Psychologie des Kriegsgefangenen. 1918. Rascher and Cie., Zurich. Fr. 1.60.

show a marked resemblance in this respect. In the German camps the prevailing feeling is one of mistrust, which especially takes the form of suspecting those who bring the post. In camp jargon, the postal officials are supposed to be always "trying it on," which is an inadequate translation of the German "Schiebung." The word constantly recurs in the records of the camp satirists. Briefly, the camp community consists of people who hope and wait together, and in so doing become wearied in mind and soul. Some find outlet in gambling, many in the familiar occupation of "grousing." Rumour plays a large part in camp life. Reports which are not at first actually believed circulate freely, so that the whole camp population may pack their things at night in preparation for a departure on the morrow, of which there was no reasonable prospect. Ruhleben has been described by an inmate as the "City of Futility." Even the best-educated has to struggle to perform mental work of any kind. Concentration becomes ever more difficult. Restlessness sets in, with mental fatigue, on the slightest exertion, whether of mind or body. Lack of memory is a frequent complaint. The depression as it increases involves disinclination to speak, and gradually the full picture develops of what is called "Stacheldraht-Fieber," and familiarly "grauer Vogel," or in French "cafard." Dr. Vischer found many grades of the affection, but is unable to give any idea of the proportion of severe cases. He instances 3 out of 30 in one hut, 50 out of several hundred in one camp. Cases are more marked as well as more numerous among internés than prisoners of war for the reason, Dr. Vischer thinks, that the former are often people who left their homes in order to find a freer existence elsewhere, and are therefore peculiarly intolerant of restraint. His statement is noteworthy that bad and even brutal treatment does not produce the disease, while good treatment does not keep it in check. Even a charming site for the camp is no prophylactic, as those will guess who have had to deal with sick folk kept for long periods away from home in beautiful surroundings. In regard to recovery he can say but little, except that the condition is not cured at once on leaving the camp. When it is in any way highly marked recovery may require a long time. Many of the internés gave him the impression of broken people. An old general who visited a number of his own officers and privates interned in Switzerland frankly admitted that he could not understand them, nor they him. The latter part of Dr. Vischer's monograph is given up to an interesting comparison of barbed-wire disease with other similar conditions. Napoleon in St. Helena suffered from an "irritation nerveuse considérable." The "mentalité grégaire" of isolated military colonies, the mass illusions of seamen becalmed on the equator, the trivial quarrels of polar explorers, the frequent neurasthenia noted in the French maritime service: all these he finds nearly akin. In all may appear the irritability, the ideas of suicide and persecution, the various obsessions, and the desire for solitude and isolation. The polar explorer has the most intimate points of similarity with the prisoner of war, with the great difference that his incarceration is voluntary. Dr. Vischer concludes with an expression of thankfulness at the share which Switzerland has taken in mitigating the prolonged isolation of the war prisoner.

THE MEDICAL SERVICE OF THE ROYAL AIR FORCE.

WE publish in another column a letter from Sir Arbuthnot Lane, Dr. G. A. Sutherland, and Mr. Joynson-Hicks, M.P., calling attention to the announcement made in Parliament last week by Major Baird, Under Secretary of the Air Ministry, in respect of the appointment of the Medical Administrator of the Medical Service of the Royal Air Force. The letter exposes exactly a situation of considerable anxiety. Not a word in it suggests that the appointment has been offered to an officer who has not the proper qualifications, and as a matter of fact the record of the officer in question, Colonel Fell, R.A.M.C., is favourably known. But Sir Arbuthnot Lane and his co-signatories call attention to the fact that no guarantee is forthcoming either from Colonel Fell himself or from Major Baird, speaking for the Royal Air Force, that under Colonel Fell's administration the scientific prospects of the Medical Service of that Force will be maintained in the promising position laid down by the newly devised conditions of the Service. These conditions were published in THE LANCET, Sept. 28th, and were read with high satisfaction by the medical profession as representing an improvement from the scientific point of view upon any terms which have hitherto been offered to the medical profession when engaged on naval, military, civil, or administrative work. Our remarks upon the conditions might well have formed the text for the letter in our columns from Sir Arbuthnot Lane, Dr. Sutherland, and Mr. Joynson-Hicks. The conditions of the Royal Air Force Medical Service, following on the Report of the Watson Cheyne Committee, make proper room for the allocation of all the medical officers of the new Service to occupations for which they are fitted, and secure the promotion by selection of particular men for particular work. To say, as Major Baird did in Parliament, that Colonel Fell will be guided by the principles of the Watson Cheyne Report is not enough. An excellent set of conditions has been devised by a strong Committee, has received the approval of the sister services and scientific laymen; to learn that they may form a guide to the conduct of the Service is to arouse a very natural suspicion that the Report of the Committee is going to be set aside, how, when, and where it may suit the incoming administration. Why can this natural suspicion not be removed?

RECONSTRUCTION IN NEUROLOGY.

OUR present ideas upon biological evolution have resulted in large measure from the work of Darwin and Spencer. Shortly after the publication of their writings workers in all branches of science—zoology, physiology, sociology, clinical medicine, and the rest—began to see the application of the principles of progressive change and evolutionary adaptation to their own particular problems, but until recently little coördination of the results obtained along these various lines of investigation had taken place. Few clinicians, for example, were conversant with the works of Marshall Hall, Balfour, Foster, Lankester, and Gaskell, whilst to laboratory workers the generalisations of Anstie, Laycock, and Hughlings Jackson from cases of disease were almost unknown. In the "seventies" and "eighties" the English school of neurology was still dominated by physiological conceptions, but with the discoveries of motor cerebral localisation and its

implications by Ferrier, Horsley, Gotch, Mott, and others anatomical and structural conceptions gained the upper hand. Now, however, the pendulum is swinging back again, and principles deduced from careful clinical investigations correlated with the findings of experimentalists are taking their proper place. This subtle change in the attitude of the neurologist not only to disease but also to its general effect upon the patient is ably described by Dr. Henry Head in his presidential address before the Neurological Section of the Royal Society of Medicine, which we print on another page. This change, in which Dr. Head has himself played no mean part, really began with the foundation by Michael Foster of the Cambridge School of Physiology. A band of workers whom he collected around him devoted themselves to the problems of nervous activity, but for many years to the bulk of the medical profession their findings remained a closed book. Even now few practitioners are fully aware of the light which the experiments of Gaskell, Sherrington, Anderson, Langley, Dale, Keith Lucas, and others throw upon the every-day problems of general practice; the essential message of Hughlings Jackson's writings in THE LANCET and *Brain* was not intended to have special appeal, but thirty years ago the general audience must have been small. To Jackson the inner meaning of disordered process was of greater importance than the obvious disability. Following him, English neurologists are beginning to see the fundamental importance of the functional adaptation shown in the integrative action of the nervous system and mind, and in dealing with the injuries, diseases, and disorders of the nervous system resulting from the stresses of war, the universal application of this principle has forced itself upon our notice. Nervous, mental, psychological, and sociological problems all illustrate the principles of incomplete adaptation. Dr. W. Aldren Turner, in his paper on the Neuroses and Psychoses of War, published in last week's issue of THE LANCET, stated that all neuroses, whether of the individual or of the nation, are the consequences of a failure of psychological adaptation or readjustment to environmental conditions. Such functional failure of adaptation can only be properly faced when the principles underlying it are kept constantly in view. No static solution of these problems is possible, and no scheme can command success which does not allow of progressive evolutionary change towards more complete adaptation. This principle also has its application in the wider fields of national reconstruction.

BOTULISM DUE TO CANNED VEGETABLES.

THE form of food poisoning known as botulism was first described in Germany, where it was found to be due to infection of meat or fish with the *Bacillus botulinus*, ham or sausage (as the name implies) being the usual source of the poisoning. In the *Journal of the Canadian Medical Association* for October, Captain E. C. Dickson, C.A.M.C., has published an important paper from the Laboratory of Experimental Medicine, Stanford University Medical School, San Francisco, in which he shows that since December, 1913, it has been recognised in the United States that botulism may be due to vegetable foods. In that month, as already recorded in THE LANCET of August 24th, p. 246, an outbreak of food poisoning of the botulinus type occurred at a "Sorority house" at Stanford University, in which 12 persons were poisoned by eating a salad prepared from home-canned beans. It was not proved that the beans were infected with the *B. botulinus*, but a series of experiments were made which showed that the toxin of the bacillus may be formed in mediums prepared from peas, beans, corn, asparagus, artichokes, peaches, pears, apricots, and prunes. Records were then collected of a series of outbreaks in which poisoning was caused by one or other of these vegetables or fruits, in all cases home-canned. Botulism differs from the usual type of food poisoning in that the central nervous system is essentially involved. It is not an infection but an intoxication, being due to a toxin somewhat analogous to the toxins of diphtheria and tetanus, which is formed in the food before it is eaten. It is never formed in the body as the optimum temperature for the bacillus is 24° to 28° C., and the toxin is not formed at 37·5° C. (the normal body temperature). The prevalence of the toxin in American home-canned vegetables and fruits is due to the fact that methods of sterilisation are not sufficient to kill the spores. The common practice is to immerse the filled jar in boiling water in a wash boiler for from two to three hours. But experiments show that emulsions of the spores resist immersion in boiling water for more than two hours. Very few outbreaks have been due to commercially canned vegetables, because in the United States vegetables are sterilised with steam under pressure at a temperature of 240° to 250° C. In all the cases of poisoning the food was not cooked before it was eaten. It has been shown that the toxin is destroyed if heated to the boiling-point, and that contaminated food is safe, so far as botulism is concerned, if cooked before it is eaten. In a number of instances portions of contaminated food have been cooked and eaten without ill-effect, while the remaining portion has been served as a salad and caused fatal poisoning. It appears that food which shows signs of spoilage, and for this very reason may be canned, is particularly dangerous. The process of home canning is not common in this country, which perhaps accounts for immunity from this form of food poisoning.

THE EFFICIENT TEACHING OF NURSING.

Dame Ethel Becher was only voicing the general feeling of the nursing world when, at a recent complimentary luncheon, as matron-in-chief of Queen Alexandra's Imperial Military Service, she spoke of the high ideals which the nurses of this country have always kept before them. It is in the translation of these ideals to actual practice that the difficulty is encountered. At present, apart from the lectures given by the medical staff, instruction in nursing methods is largely of a haphazard character and left to tired ward-sisters and over-burdened matrons, the results naturally being often disappointing to pupil and teacher alike. Matrons and sisters often do not know how to teach because they have not themselves been taught. The appointment of sister-tutors in connexion with training schools would ensure efficient instruction in nursing methods, and the College of Nursing, Ltd., has been enabled to offer through the Nation's Fund for Nurses three studentships, valued at 100 guineas each, in order to facilitate these appointments. Many hospitals and Poor-law infirmaries are prepared to appoint nurse-instructors or

sister-tutors, and it is to be part of the constructive work of the College of Nursing to qualify the trained nurse for these posts. Delay in State registration need not prevent progress in the direction of desirable constructive work. There is ample reason why it would be better to offer these studentships rather than to await the actual end of the war, or the great processes of rearrangement that will follow, yet for the moment prompt action has debarred nurses on active service from competing. The training schools have lost some of their best teachers, and the probationers are already suffering from this loss. The Entrance Examination for the studentships was held at King's College for Women on Sept. 3rd, 1918, and included two papers, one on general knowledge and the other on purely nursing topics. Two of the successful candidates come from a London school, the third from the Royal Infirmary, Manchester. The course at King's College for which the studentships are granted is an experimental one, subject to improvement from year to year. The nurses will derive benefit from working in the College with students of wider outlook, and the contact will help to break down the too cloistered attitude of the nurse's mind. We welcome the institution of these studentships and hope that next year they may be increased. Lady Cowdray has offered a special studentship for Aberdeen nurses.

Professor J. G. Adami, Colonel, C.A.M.C., has been appointed one of the Canadian representatives upon the permanent Inter-Allied Committee for the Treatment of the Disabled Soldier, and is attending the Conference now sitting in Paris.

THE death is announced, at the advanced age of 94 years, of Sir Hermann Weber, who graduated in medicine at the University of Bonn in 1848 and became a Fellow of the Royal College of Physicians of London in 1859. To him we largely owe the beginnings of the modern science of climatotherapy.

THE fourth annual report of the Medical Research Committee of the National Health Insurance has just been issued in the form of a pamphlet of 80 pages (Cd. 8981. Price 4*d*.). The report covers the work of the year ending Sept. 30th, 1918. We are indebted to the Committee for a further summary of work done abroad on the epidemiology and bacteriology of influenza.

A MEMORANDUM ON INFLUENZA

FROM THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

IN view of the alarming and contradictory reports of the present epidemic of influenza that have appeared in the public press, the Royal College of Physicians of London has made the following authoritative statement in the public interest:—

[MEMORANDUM.]

The past few weeks have now afforded sufficient experience to permit some positive statements to be made. Though the epidemic shows signs of abatement in London, it is still severe elsewhere; moreover, its after-effects call for intelligent anticipation.

The present epidemic is virtually world-wide, irrespective of race, community, or calling. Similar world-wide epidemics occurred in 1803, 1833, 1837, 1847, 1890. The long intermission since the last widespread epidemic had already made an early reappearance probable, but the conditions of epidemic prevalence of influenza are too obscure to allow of precise prediction.

This outbreak is essentially identical both in itself and in its complications, including pneumonia, with that of 1890. The disproportionate occurrence of a special symptom, a well-recognised phenomenon in the case of epidemics—as, for example, nose bleeding in the present epidemic—does not invalidate this statement. The present epidemic has no relation to plague, as some have suggested.

Although there can be no question that the virus of influenza is a living organism, and capable of transference from man to man, yet the nature of the virus is still uncertain. It is possibly beyond the present range of microscopic vision. The bacillus discovered by Pfeiffer, commonly known as the influenza bacillus, has in the past been regarded as the probable cause, though on insufficient evidence. There is doubt as to the primary part it plays in the disease, important though it probably is as a secondary infecting agent. Pfeiffer's bacillus, the pneumococcus, and above all in this epidemic the streptococcus, seem to be responsible for most of the fatal complications of influenza.

Infection is conveyed from the sick to the healthy by the secretions of the respiratory surfaces. In coughing, sneezing, and even in loud talking these are transmitted through the air for considerable distances in the form of a fine spray. The channels of reception are normally the nose and throat.

It is manifest that the closer the contact the more readily will this transmission occur; hence the paramount importance of avoiding overcrowding and thronging of every sort, whether in places of public resort, public conveyances, factories, camps, dwelling rooms, or dormitories.

The sum of available evidence favours the belief that the period of incubation is about 48 hours or even somewhat less.

The dangers of influenza are gravely increased by the complications, and much can be done to avoid or to mitigate these. Such complications may develop insidiously, and without previous signs of severe illness.

Carefulness does undoubtedly decrease, and carelessness increase, both morbidity and mortality; it is important, therefore, that the public should have a clear idea of such measures of personal prophylaxis as are available against infection; larger measures of public health, administered by Government or local authorities, stand outside the scope of the present Memorandum. The individual must be taught to realise and acquiesce in his duty to the community.

Well-ventilated airy rooms promote well-being, and to that extent, at any rate, are inimical to infection; draughts are due to unskilful ventilation and are harmful; chilling of the body surface should be prevented by wearing warm clothing out of doors.

Good nourishing food, and enough of it, is desirable; there is no virtue in more than this. War rations are fully adequate to the maintenance of good health, though they may not afford just the particular articles that each fancy demands. Alcoholic excess invites disaster. Within the limits of moderation each person will be wise to maintain unaltered whatever habit experience has proved to be most agreeable to his own health.

The throat should be gargled every four to six hours, if possible, or at least morning and evening, with a disinfectant gargle, of which one of the most potent is a solution of 20 drops of liquor sodæ chlorinatæ in a tumbler of warm water. A solution of common table salt, one teaspoonful to the pint of warm water, is suitable for the nasal passage; a little may be poured into the hollowed palm of the hand and snuffed up the nostrils two or three times a day.

Since we are uncertain of the primary cause of influenza no form of inoculation can be guaranteed to protect against the disease itself. From what we know as to the lack of enduring protection after an attack, it might in any case be assumed that no vaccine could protect for more than a short period. But the chief dangers of influenza lie in its complications, and it is probable that much may be done to mitigate the severity of the affection and to diminish its mortality by raising the resistance of the body against the chief secondary infecting agents. No vaccines should be administered except under competent medical advice.

No drug has as yet been proved to have any specific influence as a preventive of influenza.

At the first feeling of illness or rise of temperature the patient should go to bed at once and summon his medical attendant.

The early stages of an attack are the most infective, but infection may persist throughout the illness, and segregation should be maintained at least till the temperature is normal.

Relapses and complications are much less likely to occur if the patient goes to bed at once and remains there till all fever has gone for two or three days; much harm may be done by getting about too early. Chill and over-exertion during convalescence are fruitful of evil consequences.

The virus of influenza is very easily destroyed, and extensive measures of disinfection are not called for. Expectoration should be received when possible in a glazed receptacle in which is a solution of chloride of lime. Discarded handkerchiefs should be immediately placed in disinfectant, or if of paper burnt.

The liability of the immediate attendants to infection may be materially diminished by avoiding inhalation of the patient's breath, and particularly when he is coughing, sneezing, or talking. A handkerchief should be held before the mouth and the head turned aside during coughing or sneezing. The risk of conveyance of infection by the fingers must be constantly remembered, and the hands should be washed at once after contact with the patient or with mucus from the nose or throat.

Each case must be treated, as occasion demands, under the direction of the medical attendant.

No drug has as yet been proved to have any specific curative effect on influenza, though many are useful in guiding its course and mitigating its symptoms.

The Memorandum closes with the statement that in the uncertainty of our present knowledge considerable hesitation must be felt in advising vaccine treatment as a curative measure. A warning is added that a period of enfeeblement following an attack of influenza should never be disregarded, as it is apt to mask the presence of other morbid conditions.

Correspondence.

"Audi alteram partem."

THE MEDICAL SERVICE OF THE R.A.F.: PRINCIPLES OF PROMOTION.

To the Editor of THE LANCET.

SIR,—Major Baird's statement in the House of Commons on Nov. 4th that the appointment of Director of the Medical Service had been offered to Colonel Fell, who would act on the principles of the Advisory Committee's Report, hardly coincides with the position as we see it at the moment, and the matter is of such vital importance, not merely to the future of the Air Service, but to the whole medical situation throughout the country, that we enture to trouble you with the following remarks.

The Report of the Flying Services Medical Advisory Committee, to give it its full title, was a long and carefully considered document, unanimously passed on Nov. 29th, 1917, not only by the civilian members, but also by the representatives of the Admiralty, the War Office, and the Air Service. Put shortly, the whole object of this Committee in formulating their scheme for an Air Medical Service was that promotion should be by medical efficiency, and not, as in the R.A.M.C., by administrative capacity.

The most important proposal involved the formation of a service in which specialisation and efficiency, assisted by a wise system of competition, would afford to the State a body of expert medical men who would rise in rank independently of the necessity of discarding the practice of their profession in order to assume administrative duties, which system prevails in the existing medical services.

The Report further contemplated the appointment of three Medical Officers for Training, for Air Command, and for Hospital Work, and four officers for the supervision of general pathology, sanitation, statistics, and medical supplies.

We will not trespass upon your space to describe in detail the proposals of the Committee; suffice it to say that in our opinion the ground was laid for a Medical Service superior to that of any existing force.

As part of these proposals a Medical Administrative Committee was instituted in order to assist the Medical Administrator of the Air Force in carrying into effect the principles of the Report. They have devoted nearly a year to this work, which is now to be thrown on one side.

It is known, moreover, that after the war the medical administration of the three Services will in all probability be amalgamated into one Imperial Medical Service, and it is of the highest importance from every point of view that the administration of this united Service should be scientific in the best sense of the term. Moreover, it is more than probable that the new Civilian Medical Service, which will presumably be the outcome of the Ministry of Health, will, in fact must, be founded on either the lines of the R.A.M.C. or the lines of the Air Force Medical Service, and again we suggest that it is of vital importance to such Civilian Service to commence on what we conceive to be the right lines.

Now, however, the work of the Advisory Committee is being undone by the Air Council. The office of Medical Administrator has apparently been offered to Colonel Fell (a gentleman of whose administrative abilities we say nothing, but who, during the war, has occupied himself simply and solely with administration in various areas), with freedom from the control of the Medical Administrative Committee. It is possible that he may work on the principles of the Report, but it is hardly likely, particularly as Major Baird admits that the Administrative Committee has as such been dissolved, and we can find no trace of its retention in an advisory capacity as suggested by the Under-Secretary; in fact, at the last meeting of the Committee on Oct. 21st the chairman stated that the Committee was automatically dissolved and that there would be no further meeting.

Surely the Air Board will not, without consulting the Committee, which took so much pains to lay the proper foundations of the Medical Service, tear up all its work and lose the opportunity of founding a really scientific Medical Service for the new Air Force.—Yours, &c.,

W. ARBUTHNOT LANE, } Members Medical
G. A. SUTHERLAND, } Advisory Committee.
W. JOYNSON-HICKS,
Chairman, Parliamentary Air Committee.

Nov. 7th, 1918.

THE TREATMENT OF INCIPIENT MENTAL DISEASE.

To the Editor of THE LANCET.

SIR,—Among the proposals for reconstruction which are to the fore is one for legalising treatment of persons who are suffering from incipient mental disease. The Board of Control have devoted some space to the subject in their fourth annual report recently issued, where they suggest (amongst other things) the amendment of the present law (1) to enable incipient cases of mental disorder to receive treatment in general or special hospitals, mental institutions, &c., for not more than six months without the necessity for certification under the Lunacy Acts; (2) to permit the establishment at general hospitals of sections for both in- and out-patients for the early diagnosis and treatment of incipient cases; and (3) to extend to public asylums the principle of voluntary admission which now obtains with respect to private asylums.

It does not appear to be generally known that the London County Council has already to some extent anticipated the first and third at least of these suggestions in connexion with its proposed use of the Maudsley Hospital at Denmark Hill. This hospital, originated by the late Dr. Henry Maudsley, towards the erection of which by the Council he generously contributed the sum of £30,000, is designed for the early residential treatment of acute cases of mental disorder and for the provision of advice and treatment for out-patients. It has not yet been used for the purpose intended, for it was taken over by the War Office before the building was completed, and is now being used for treatment of neurasthenic and shell-shock cases arising from military service. In anticipation of its use, however, upon the lines originally laid down, the London County Council, in its General Powers Act, 1915, obtained authority to receive and treat voluntary boarders at the hospital. The powers obtained were somewhat restricted, but they will permit the Council, when the hospital reverts to the use for which it was designed, to receive as patients persons who desire *voluntarily* to submit themselves for treatment. It is the fervent hope of many who are associated with the care and treatment of mental cases that this power, together with the establishment of a clinic at the hospital, will afford means of early treatment, which may avoid the necessity for subsequent certification in many cases, and will further help to spread a general knowledge of mental diseases which is often, for a variety of reasons, not found to-day.

I am, Sir, yours faithfully,

R. J. COOPER,
Chairman of the Asylums and Mental Deficiency Committee of the London County Council.

County Hall, Spring Gardens, London, S.W., Nov. 6th, 1918.

To the Editor of THE LANCET.

SIR,—On Oct. 5th you published a letter of mine dealing with the early diagnosis and treatment of the insane. Judging by private correspondence and conversation which I have had since then, I think I ought to explain in more detail what I intended. I pointed out the difficulties that beset the general practitioner in the diagnosis and treatment of insanity in its early stages. When the reform of lunacy practice comes about I hope that it will be found possible to provide expert assistance for the general practitioner. What I would suggest would be that in any case of suspected insanity the practitioner in attendance should have the right of calling in an appointed specialist, just in the same way as he can now do in the case of suspected tuberculous disease. In this case it should be arranged that the medical attendant would actually meet the specialist in consultation. The medical attendant would then have the advantage of a really useful clinical lecture, and the advantage would extend not only to the patient, but to the expert who would often see what he now seldom has an opportunity of seeing—the patient in the early stage of his illness in his usual and ordinary surroundings; and he could not fail to gather useful information as to the cause of his attack and guidance for treatment, which must vary with the circumstances of different patients.

I do not see what other chance there is for a specialist to get these patients at this stage at a clinic where he could demonstrate their condition to the practitioners who are anxious to be taught. It has always seemed to me that, in a very large proportion of diseases, a clinic in a patient's natural and usual surroundings must have a great advantage

over any other form of teaching. A question might arise as to who should be the expert. The answer to this is not the intention of my letter, but I would suggest that the most suitable person to call in would be the medical superintendent of the county asylum of the area in which the patient is residing. It would be impossible for any local authority to suspect him of having any sordid interest in any treatment he might recommend.—I am, Sir, yours faithfully,

Bradford-on-Avon, Oct. 28th, 1918. CHAS. E. S. FLEMMING.

THE VISITS OF CONSULTANT PHYSICIANS TO PRIVATE SERVICE LUNACY PATIENTS.

To the Editor of THE LANCET.

SIR,—I have been in practice now for 45 years and have done consulting work in mental medicine for over 32 years. During the whole of that period I have seen many patients at the request of their relatives in public asylums, registered hospitals, licensed houses, private care, and in many nursing homes, and until this case my visits have never been opposed but rather welcomed, and I can look back to many very happy hours spent in some of these institutions. I fear from what I hear from several medical men this has not always been the case in their experience.

Not long ago I was asked by a brother of a private service patient in a county asylum to visit and report on his brother's case. I agreed to make this consultative visit and asked him to write to the medical superintendent of the said institution asking for permission for such visit. I also wrote asking the medical superintendent for permission to visit this patient. I received a letter from the medical superintendent stating that such a visit of an outside practitioner to any patient in his asylum would be creating a precedent and that he must refuse permission. I at once pointed out Sec. 47 of the Lunacy Act which dealt with this question and also wrote to the Board of Control. The brother of the patient wrote to the Board also, pointing out the same section, and referred to the report of the Select Committee on admission of friends, relatives, and medical men to patients in institutions for the insane. The Board of Control refused to intervene on the ground that it would create a precedent for an outside practitioner to visit any patient in a public asylum. To this a solicitor replied, saying that unless an order was given for my visit under Sec. 47 of the Act he should immediately apply for a mandamus. A similar request from the wife of the patient was enclosed. By return of post an order for my visit was sent. I wrote to the medical superintendent, telling him the day and time I was coming down, and asking him to let me see the entries in the case-books and the certificates upon which the patient was received as a private service patient. I also asked if he would kindly tell me the best means of getting quickly from the railway to the asylum. To this letter I received no reply. I arrived at the asylum at about the time stated in my letter, and was told by the head attendant that he had orders to allow me to see the patient. I asked that I might first see the entries in the case-book *re* the case, and also the certificates upon which he was received. His answer was that he had orders not to show me these. I found the patient in bed. I asked why he was in bed, and was told, "To see you." I examined him, and all I could get from him was that he wanted to get back to his wife and family, and to work for them; that he had tried to commit suicide when in a hospital at Cambridge, and that he felt he was buried alive. I then asked several questions of the attendant in charge, who was unable to reply to them. The medical officer in attendance on the patient refused to see me.

The solicitor then wrote to the Board of Control, telling them what had happened and asking for another order with special instructions that I was to see the entries in the case-book and the certificates in respect of the patient, and some medical man. To this letter the Board of Control answered that I had already visited the patient and that there was no reason for granting another order. The matter is now before counsel as to the next step to be taken.

I admit that the Board of Control have the right to make the order for such visits as I proposed, and that they reserve that right lest undesirable persons should seek admission to patients in asylums, but I hardly see how a medical consultant can be considered an undesirable visitor.

I am, Sir, yours faithfully.

LIONEL A. WEATHERLY, M.D.

Winsley House, Bournemouth, Nov. 7th, 1918.

PHTHISIS IN FACTORY AND WORKSHOP.

To the Editor of THE LANCET.

SIR,—As chairman of the Subcommittee on Phthisis in Relation to Occupations appointed by the Medical Research Committee, I would point out that Dr. Benjamin Moore's article in your issue of Nov. 9th was a contribution to the work which is being carried out by this committee of the Medical Research Committee, which was started in 1914 under the chairmanship of Dr. Addison, and the members of which now are Dr. Brownlee, Professor W. Bulloch, Dr. Edgar Collis, Sir Walter Fletcher, Captain Major Greenwood, Dr. Benjamin Moore, and Dr. Leonard Hill. A report of the Subcommittee on the Boot and Shoe Industry was issued by the Medical Research Committee in 1914, and therein the idea of the factory sanatorium was put forward—an idea which arose out of a conversation between Dr. Edgar Collis and Dr. Eslemont. In a paper published in the Proceedings of the Tuberculosis Conference at Leeds in 1913 Dr. Edgar Collis pointed out that the incidence of tuberculosis among adult males, as compared with that of females, suggested an industrial influence, and that the lack of this difference for males and females in agricultural areas supported this suggestion. Dr. Brownlee, in a report recently published by the Medical Research Committee, further and extensively examined the incidence of phthisis in rural and industrial districts. Dr. Benjamin Moore now concentrates attention on, and still further elucidates, this important matter.

I am, Sir, yours faithfully,

Loughton, Nov. 11th, 1918. LEONARD HILL.

DISPENSARY SUPERVISION IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—Dr. Geo. Jessel's paper on the above subject in your issue of Oct. 26th raises the very important question, Are the tuberculosis dispensaries really doing anything to reduce tuberculosis? Dr. Jessel does not, naturally, attempt to answer this question, but only claims that, in his experience, "dispensary supervision has resulted in a considerable measure of success." What may be the kind and degree of this success is not made clear in his paper, as his own figures show that, with the same staff of nurses, the number of cases under observation increased from 1164 in 1916 to 1615 in 1917. That this increase cannot be attributed to greater accuracy in notification Dr. Jessel has himself pointed out.

Dr. Jessel assumes that the possession of a separate bedroom is synonymous with "complete isolation," and from this concludes that "home treatment is thus possible and safe in about 70 per cent. of cases occurring in the industrial areas of Lancashire at any rate." Unfortunately, a long and intimate acquaintance with the industrial conditions of Lancashire has convinced me that this assumption is entirely fallacious. A consumptive who is not bedridden will, of course, make his way to the fire in the "living-room," and when he becomes bedridden the very warmth of Lancashire people's family affection will effectually prevent his being left in "splendid isolation."

The fact has to be faced that vital statistics show no decline whatever either in the incidence of tuberculosis or the mortality from this cause, and if, as Sir James Barr asserts, our present methods are not only futile but mischievous, it will not do to hide our heads in the sand of such phrases as "studying every patient in relation to his environment." Dr. Jessel emphasises the importance of consultation with the "general practitioners," and it is satisfactory to learn that the profession is thus giving a fair trial to the system. I have no doubt that such consultation with experienced practitioners must be of value to officials who, prior to the passing of the Insurance Act, were themselves, as a rule, either general practitioners or medical students.

I am, Sir, yours faithfully,

FRED. E. WYNNE,

Medical Officer of Health, Wigan; President, N.W. Branch, Society of Medical Officers of Health.

Nov. 7th, 1918.

THE Royal Dental Hospital, Leicester-square, has received a donation of £300 from the Alexandra Day Committee, being the amount allocated to this hospital from Her Majesty Queen Alexandra's Special List.

Obituary.

LIEUTENANT-COLONEL E. F. HARRISON, C.M.G.

IF the death of Colonel Harrison had occurred nine months ago his loss would have been a national disaster. As it is, worn out by unremitting toil of the last three and a half years, he has died in the moment of the victory in the winning of which he played so great a part. Only a few people, and the public not at all, have any idea of the immense debt that the country owes to Harrison. They have dimly apprehended the fact that very soon after the introduction of gas warfare the British established a preëminence in methods of defence which has been retained up to the end. In this work of gas defence Harrison was the guiding brain; not only were the methods employed for the greater part his invention, but the enormous organisation necessary for their utilisation by our troops was due to his business capacity and brain power. It is impossible to reckon the thousands of lives which have been saved by his work; without this we might more than once have met with disaster under the influence of the new chemical poisons continually being introduced by our enemies. During practically the whole of this time Harrison was compelled to work in a subordinate position. Not till a week before his death, in the fifth year of the war, had he been appointed Controller of Gas Services. If this had happened only a year ago we should not have remained hopelessly behind the Germans in our gas offensive, and under Harrison's direction we might have achieved as notable a success in the offensive use of gas as we have throughout enjoyed in the defence against gas.

Harrison was a man of acute brain, and with a wide knowledge of his subject, endowed with the spirit of an investigator, he would have made a name for himself in pure chemistry had he elected to apply himself to research. Previous to the war, however, he had been engaged in work as an analytical chemist and was chiefly known to the public as the author of two works on "Secret Remedies" which had been published by the British Medical Association. His training, however, had made him peculiarly fitted for the task to which he was called in the nation's hour of trial. He had acquired technical skill, methodical habits of work, a great knowledge of chemical material, and a wide acquaintance with chemical processes and with sources of supply. Although endowed with indomitable resolution, he was modest and unassuming in manner, so that he was able to get things done without giving offence to those whose deficiencies he had to supplement. This characteristic of his was invaluable to him in his dealings with the War Office. When met by the obstructions of slackness and incompetence in other departments he slowly gained his way by steady, quiet persistence. Hindered and again in the organisation of his department, and in obtaining the necessary personnel as well as the proper rank for them which would have enabled him to delegate part of his arduous duties, he got the essential work done by himself doing the work of two men. It is hardly to be wondered at that, when the stroke came in the form of an attack of influenza, it found his reserve forces exhausted and that the worn-out machine succumbed.

Throughout his work Harrison was actuated by the purest patriotism, and there was never any trace of self-seeking or desire for honours. As soon as he recognised that the war was going to last some years he threw up his private work and enlisted as a private in May, 1915. With the formation of the Chemical Corps he was made a corporal in this corps. Almost immediately afterwards—in July, 1915—he was given a commission and appointed to work with a number of other chemists in the R.A.M. College. Here his first duty was to assist in the experiments being made at that time on the improvement of the gas helmet. In September he was appointed to act as head of the chemical department, and 12 months later was made officer in charge of the Anti-gas Department. When he came to the R.A.M. College the gas helmet had been recently introduced. Harrison, while working on the improvement of this helmet and at securing some standard of excellence in its manufacture, was continually striving to obtain a means of protection, not only against phosgene, chlorine, and similar gases, but also against all possible poisonous gas. The first result of his endeavours was the production of the large box respirator, often spoken of as "Harrison's Tower," which was intended only for the use of the special Chemical Corps. The increasing concentration in the phosgene used by the enemy and the introduction of new poisonous gases made it evident that an equally complete protection would have to be provided for all the troops, and experiments carried out by Harrison and under his guidance finally led to the adoption of the present type of box respirator. Having settled upon the type, it was necessary to ensure the manufacture, not only of the chemicals, but also of the multifarious parts of each respirator on an enormous scale. The chemical protection involved first the working out of a method for making permanganate granules. Then it was necessary to discover the best methods of preparing charcoal, the absorptive powers of which may be altered 20 times according to the method of preparation. At first these substances were made by private firms, but their resources not proving adequate to the enormously increasing demands Harrison organised large factories where the process of manufacture was carried out under his direction. Every one of the parts had to be perfect, since any defect might lead to the loss of life of the soldier. Some idea of the magnitude of the task may be gleaned from the fact that, in addition to 15,000 workpeople directly under the Anti-gas Department, there were 120,000 engaged in the manufacture of box respirators. The perfection of the organisation and the foresight employed can be gauged from the fact that at no time did Harrison fail to respond to any increased demand, however unexpected. When the Americans failed to turn out, as they had expected, sufficient box respirators in time to equip their troops Harrison was able to supply all deficiencies. In the spring of this year there was much anxiety lest the Italian Army should be knocked out by a gas attack similar to that which initiated the disaster at Caporetto. A sudden resolution was adopted to equip the Italian Army with the British respirator, and within one month Harrison furnished the Army with a million of these respirators.

Harrison had the satisfaction of the consciousness of work well done. Though he was the driving brain and force of the whole organisation of gas defence, he had only received the rank of Lieutenant-Colonel, and shared the honour of a C.M.G. with a host of mediocrities. And yet his part in gaining our complete victory has been not inferior to that of any general in the field It is to be feared that, because he worked out of sight and because he was not a professional soldier, his great services may be forgotten. They will, however, always rank high in the memory of his friends and fellow workers, and in the proud remembrance of his children.

E. H. STARLING.

MEREDITH TOWNSEND, M.R.C.S., L.S.A.,

LATE MASTER OF THE APOTHECARIES' SOCIETY.

WE regret to announce the death, from pneumonia following influenza, of Mr. Meredith Townsend, late Master of the Apothecaries' Society of London, which occurred on Nov. 5th, at Barnes, in the house of Dr. M. Milton Townsend, his son. Mr. Meredith Townsend was born in 1847, the son of Dr. Henry Meredith Townsend, who practised in Clapham. He entered the medical school of St. Thomas's Hospital on leaving school, and qualified as M.R.C.S.Eng., L.S.A., in 1868. Going immediately into practice in the south-west of London, he was for no less than 50 years medical officer to the Kensington guardians. He resided for many years in Upper Phillimore-place, and for 35 years he was surgeon to the F Division of the Metropolitan Police and public vaccinator for Kensington. In 1914–15 he was Master of the Worshipful Society of Apothecaries, and at the time of his death represented that corporation on the General Medical Council. He was also a very active member of the executive committee of the Belgian Doctors' and Pharmacists' Relief Fund, and through his energy the Apothecaries' Society allowed their premises to become a depôt for surgical instruments which were distributed among the Belgian medical men.

Mr. Townsend only retired formally from medical practice a few weeks before his death. His widow and ten children, four sons and six daughters, all survive him.

Dr. O. Veraguth has been appointed Director of the Clinic for Physical Therapeutics in Zurich with the title of professor.

The War and After.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue :—

Died of Wounds.

Capt. J. J. Tough, R.A.M.C., qualified at Edinburgh in 1910. He held appointments at the Sick Children's Hospital and at the Royal Infirmary, Edinburgh, and prior to joining the R.A.M.C. was in practice at Accrington.
Lieut. D. W. Sinclair, R.A.M.C., attached R. Scots.
Capt. H. Dunlop, Canadian A.M.C.

Previously Reported Wounded, now Reported Died of Wounds.

Capt. N. H. Little, Canadian A.M.C.
Capt. H. P. Whitworth, R.A.M.C., attached Scottish Borderers, was a student at Guy's Hospital, London, and qualified in 1914.

Died.

Major D. Burrows, R.A.M.C., qualified at Glasgow in 1902. Prior to joining the R.A.M.C. he was in practice in Sierra Leone, where he was provincial medical officer. He died at the War Hospital, Chester.
Lieut.-Col. J. T. McEntire, R.A.M.C., qualified at Dublin in 1903 and joined the R.A.M.C. shortly afterwards.
Capt. L. T. McClintock, R.A.M.C., qualified at Edinburgh in 1901 and held an appointment at the Salop Infirmary. At the time of joining the R.A.M.C. he was in practice at Loddon, Norfolk, where he was medical officer to the Red Cross Hospital and to the workhouse, and was also public vaccinator for the district.
Capt. C. H. V. Smith, Canadian A.M.C.

Wounded.

Capt. E. Rogerson, R.A.M.C., attached K.R. Rifles.
Col. H. N. Dunn, C.M.G., D.S.O., R.A.M.C.
Capt. T. L. Bomford, I.M.S.
Capt. L. H. Fraser, Canadian A.M.C.
Capt. J. Rowland, R.A.M.C.
Capt. A. R. Hagerman, Canadian A.M.C.
Capt. M. W. Thomas, Canadian A.M.C.
Surg. D. L. Baxter, R.N.
Capt. W. G. Shakespeare, R.A.M.C.
Capt. E. T. Curran, Canadian A.M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported :—

Lieut. J. E. Stephen, The Buffs, attached Indian Infantry, killed in action, only son of Temp. Lieut.-Col. G. N. Stephen, R.A.M.C., of the staff of the *British Medical Journal*.
Lieut. H. A. Edridge-Green, R.W.F., attached R.A.F., died at Dover, only son of Dr. F. W. Edridge-Green, of Willesden, London, N.W.
Lieut.-Col. A. Thorp, D.S.O., R.A., killed in action, eldest surviving son of the late Dr. C. W. Thorp, of Todmorden, Lancs.
Acting Major E. H. S. Chapman, Indian Cavalry, died abroad of influenza, only son of Dr. H. F. Chapman, of Richmond, Surrey.
Capt. C. B. Girvin, Royal Dublin Fusiliers, died in camp in Yorkshire, only son of Col. J. Girvin, A.M.S.
Second Lieut. S. C. L. Guilding, R.F.A., died abroad of influenza, only son of Dr. L. M. Guilding, of Reading.
Lieut. W. Adam, Yeomanry, attached Machine Gun Corps, died from influenza, following on wounds received in action, third son of the late Dr. J. Adam.
Second Lieut. T. H. Hammond, M.G.C., killed in action, only son of the late Dr. T. Hammond, H.M. Prison Service, Liverpool.
Lieut. H. T. P. Moore, M.C., R.F.A., killed in action, only son of Lieut.-Col. E. J. Moore, C.B., R.A.M.C., of Blackheath, London.
Capt. H. P. D. Helm, R.A.F., late Border Regiment, eldest son of Dr. R. D. Helm.
Lieut. L. T. D. Stables, Northamptonshire Regiment, killed in action, second son of Dr. W. W. G. Stables, of Upper Norwood, London, S.E.

REPATRIATED MEDICAL OFFICERS.

The following members of the R.A.M.C., who were prisoners in Germany, have now reached England :—

Capt. W. Arnott; Capt. M. T. Ascough, M.C.; Capt. A. G. Bisset, M.C.; Capt. T. Blackwood; Lieut. A. Boyle; Capt. H. Crassweller; Capt. C. R. Crowther; Capt. S. J. Darke, M.C.; Capt. W. F. Dunlop; Capt. J. G. Elder; Capt. M. S. Esler; Capt. C. W. Fowler, M.C.; Capt. D. Gillespie; Capt. L. S. H. Glanville; Lieut.-Col. A. C. H. Gray; Capt. P. H. Green; Capt. E. H. Griffin, D.S.O., M.C.; Capt. R. M. Handfield Jones, M.J.; Capt. W. G. Harnett; Capt. G. F. P. Heathcote, M.C.; Capt. A. C. Hepburn; Capt. R. W. Hodgson Jones; Capt. C. E. P. Husband; Capt. W. J. Isbister, M.C.; Capt. G. L. Jones; Lieut. J. W. Jones; Lieut.-Col. H. B. Kelly, D.S.O.; Major J. Kennedy; Major J. S. McConnachie, M.C.; Lieut. A. M. McCormick; Capt. J. M. Mackenzie, M.C., Capt. D. Macnair; Capt. H. C. Martin; Capt. W. T. P. Meade-King; Capt. C. A. Meaden; Capt. C. Mearns; Lieut. O Le F. Milburn; Col. A. Milne-Thompson, C.M.G., M.C.; Capt. J. C. Muir; Capt. F. C. Nicholls, M.C.; Capt. W. O Brian; Lieut. F. S. O'Dowd; Capt. R. W. Pearson, M.C.; Lieut. E. S. Phillips; Capt. S. V. P. Pill; Lieut. F. J. Power; Capt. W. A. Rees; Lieut. D. Robertson; Capt. J. Ross, M.C.; Lieut. W. H. Rowden; Capt. A. B. Simpson; Capt. F. P. Smith; Capt. R. M. Soames; Capt. J. Sullivan; Capt. J. Tate; Capt. F. R. Tickle; Capt. G. Torrence, M.C.; Capt. W. Warburton; Capt. D. A. Wilson; Capt. C. Witts, M.C.

THE HONOURS LIST.

The following awards to medical officers are announced. All are members of the R.A.M.C. unless otherwise stated :—

Bar to the Distinguished Service Order.

Capt. (acting Lieut.-Col.) GEORGE PRITCHARD TAYLOR, D.S.O., M.C.—For conspicuous gallantry and devotion to duty in arranging for clearing the wounded in the forward area during an attack. He personally reconnoitred the whole area and arranged relay posts for the bearers, freely exposing himself in the front line to heavy fire while searching for wounded. Throughout the operations the wounded, thanks to his splendid zeal and devotion to duty, were cleared with remarkable rapidity.

Distinguished Service Order.

Major FREDERICK NEILL LE MESSURIER, Australian A.M.C.—For conspicuous gallantry and devotion to duty. He was continuously in the front line during both stages of an attack, assisting in collecting and arranging for the prompt disposal of the wounded to the rear. He behaved splendidly, and by his untiring efforts and a complete disregard of his own safety he greatly assisted the brigade throughout.

Lieut.-Col. ARTHUR MITCHELL WILSON, Australian A.M.C.—For conspicuous gallantry and devotion to duty during an attack while in charge of bearer divisions. He followed close on the heels of the infantry into captured villages, establishing bearer-posts, and effected the evacuation of the wounded with remarkable rapidity. He worked splendidly throughout, and by his untiring devotion to duty saved a number of lives.

Second Bar to the Military Cross.

Capt. JAMES ALWIN COLVILLE SCOTT, M.C.—For conspicuous gallantry and devotion to duty. He attended to a very large number of wounded in the open, under heavy fire from machine-guns and artillery, and it was largely owing to his skilful arrangements that the casualties were rapidly evacuated. Later on, while performing these duties, he was severely wounded by shell fire. Throughout the whole of the operations his courage and his example of self-sacrifice were worthy of high praise.

Bar to the Military Cross.

Capt. FRANK WILLIAM FAY, M.C., Australian A.M.C.—For conspicuous gallantry and devotion to duty during an attack. He was in charge of motor ambulances, and before moving them forward he reconnoitred the roads at considerable risk in his car. He remained on duty continuously for four days, exploring each route and opening up new tracks for each successive advance. By his untiring zeal and devotion to duty he enabled the evacuation of the wounded of two divisions to be smoothly continued.

Temp. Capt. ARTHUR WILMOT RAYMOND, M.C.—For conspicuous gallantry and devotion to duty. Hearing that a number of wounded men were on an exposed ridge in front, he went forward with his stretcher party, and, in spite of heavy machine-gun fire, dressed and evacuated them all. This incident was typical of his spirit, for throughout operations he displayed magnificent courage.

Capt. ALEXANDER FRAZER WILSON, M.C.—For conspicuous gallantry and devotion to duty. He attended to the wounded of a party which was caught in a sudden barrage of enemy high-explosive and gas shells, working in the open under heavy fire. He succeeded in dressing their wounds and evacuating them to hospital. His coolness and disregard of his own safety were worthy of great praise.

Military Cross.

Temp. Capt. LEO BLAKE.—During operations in connexion with a counter-attack he displayed great courage and skill in attending to the wounded at all hours of the day and night.

Temp. Capt. FERGUSON FITTON CARR-HARRIS, D.S.O.—For conspicuous gallantry and devotion to duty during an attack. He attended the wounded under heavy fire and organised bearer parties. It was due to his fine example under most difficult conditions that a large number of wounded were evacuated from "No Man's Land."

Temp. Capt. FRANCIS WILLIAM CLARK.—He dressed the wounded continually by day and by night, although his aid-post had no cover except small banks and he was constantly under heavy shell fire. His cheerful devotion to duty was a splendid example to all.

Temp. Capt. PERCY SELWYN CLARKE.—For conspicuous gallantry and devotion to duty. After an unsuccessful attack he went out into "No Man's Land" and attended to many wounded, being exposed to heavy shell and machine-gun fire the whole time. His courage and coolness were a fine example to the stretcher-bearers working under him, and encouraged them in their difficult and dangerous task.

Capt. ELMER JOHN DICKINSON, Canadian A.M.C.—For conspicuous gallantry and devotion to duty. He attended to the wounded, both our own and those of our Allies, in a first aid post close to the enemy lines under heavy fire and aircraft attacks. On two occasions enemy aircraft flying very low fired into the post, breaking the medicine bottles and causing casualties. He behaved with great coolness and courage, inspiring the men around him and keeping up the spirits of the wounded by his example.

Lieut. WILLIAM ALDRIDGE FRASER.—For marked courage and untiring zeal in carrying out his duties under heavy artillery and machine-gun fire. He inspired all his staff by his energy in organising parties to bring in wounded, thereby saving many lives.

Temp. Capt. JOHN WILLIAMSON FREW.—For conspicuous gallantry and devotion to duty. During five days' hard fighting he was indefatigable in attending to the wounded, leading his bearers forward under heavy fire to the regimental aid-posts, arranging for the evacuation of casualties and maintaining the supply of medical necessaries. His example of disregard of danger greatly encouraged his bearers, and his efforts undoubtedly saved many lives.

Temp. Capt. FREDERICK WAISTELL HIRD.—For conspicuous gallantry and devotion to duty. He remained for two and a half days in a village that was being heavily shelled and many houses of which were in flames, and attended to a very large number of wounded from our own and Allied troops. When his aid-post was set on fire he was indefatigable in his efforts to remove the wounded to a safer place. The excellent manner in which he organised stretcher parties under heavy fire undoubtedly saved many lives, and he set a splendid example to all who were working with him.

Capt. WILLIAM JOSEPH LACY-HICKEY.—For conspicuous gallantry and devotion to duty. He worked for two days and two nights practically without sleep attending to the wounded in the field and organising stretcher parties to evacuate the casualties. His work was carried out under the most difficult conditions, and he was under heavy fire the whole time. He set a very fine example of courage and endurance.

Capt. ALGERNON GEORGE ROWLEY LILFORD, Australian A.M.C.—For conspicuous gallantry and devotion to duty. He remained at his post under gas-shell and H.E. bombardment which exploded gas shells near by. His cool example and energy caused the successful evacuation of patients and saved many lives.

Lieut. GERALD ESMOND MACALEVEY.—For great gallantry and resource in evacuating casualties from rear aid-posts under heavy artillery and machine gun fire. Though frequently forced to move on account of hostile fire, he never lost touch with any of them, and it was entirely due to his untiring devotion that all the casualties were safely cleared.

Capt. DONALD WALTER McCREDIE, Australian A.M.C.—For conspicuous gallantry during an advance. His battalion was practically isolated for two days, during which he tended wounded under fire. He continually crossed machine-gun-swept spaces, after stretcher-bearers had been shot down, to attend wounded. Throughout he showed untiring energy and devotion to duty, and by his fine conduct saved many lives.

Capt. JOHN CLARK McCULLOUGH, Canadian A.M.C.—For conspicuous gallantry and devotion to duty. Under heavy shell fire, and at great personal risk, this officer continued to attend to the wounded of his own and other units until he himself was seriously wounded. On previous occasions his fine work has resulted in the saving of many lives.

Capt. (acting Major) GEORGE MORTIMER McGILLIVRAY.—For conspicuous gallantry and initiative during an attack. As officer in charge of bearers, he personally visited all regimental aid-posts and maintained a continuous evacuation of casualties. He also, under heavy fire, led a bearer party to clear a wood of wounded. He behaved splendidly and saved a large number of lives.

Capt. MALCOLM ARCHIBALD McKECHNIE, Canadian A.M.C.—For conspicuous gallantry and devotion to duty. He worked with untiring perseverance in evacuating the wounded from the field of action, under heavy fire, until he was seriously wounded himself. It was largely due to his efforts and self-sacrifice that the casualties were so successfully and rapidly evacuated from the area.

Temp. Capt. JAMES FRANKLIN McLAY.—For great courage and devotion to duty in tending to the wounded under heavy shell fire. His conduct was worthy of the highest praise.

Temp. Capt. MICHAEL MURPHY.—For conspicuous gallantry and devotion to duty during an attack. He worked continuously for 36 hours attending the wounded under heavy fire and evacuated a large number of cases. It was due to his splendid energy that the evacuation of the wounded was so successfully carried out.

Capt. JOHN MILLIE PRINGLE.—For conspicuous gallantry and devotion to duty. He attended to the many casualties of two battalions, working in the open under heavy fire for 36 hours without rest. During 10 days' hard fighting he was untiring in his efforts, and it was very largely due to his excellent organisation in one locality that the wounded of five battalions were successfully evacuated. He set a splendid example.

Temp Capt. DANIEL FALCONER RIDDELL.—For conspicuous gallantry and devotion to duty in tending to the wounded under trying conditions. His skill and coolness under fire undoubtedly saved many lives.

Temp. Capt. (acting Major) GAVIN STIELL.—For conspicuous gallantry and devotion to duty. He went with a party of volunteers to an Allied field artillery position which was being heavily shelled, the ammunition also of the dump in the vicinity exploding, as it was on fire, and superintended the dressing and removal of the casualties. He was quite regardless of his own safety, and worked with an energy and determination that undoubtedly enabled the rapid evacuation of the wounded to be completed. He was eventually wounded himself.

Temp. Capt. DENNIS JEFFCOTT STOKES.—After a shell had burst in his dug-out, killing or wounding all those present, he continued without any hesitation to dress the wounded, notwithstanding his exposed position and the enemy artillery fire. His cheerfulness and courage were instrumental in saving many lives.

Temp. Capt. WILLIAM HENRY SUTCLIFFE.—For conspicuous gallantry when acting as ambulance bearer officer. He superintended the clearing of wounded under heavy fire, and successfully evacuated all casualties from the posts under very trying conditions. Though several of his stretcher-bearers were wounded, he kept in constant touch with the units in the line. His untiring devotion was a splendid example to the men.

Temp. Capt. JOHN CHARLES WOOTON.—He attended to the wounded throughout the day, in spite of gas and heavy shell fire. On one occasion the roof of the aid post was blown in on the top of him. Later, when his aid-post was the furthest forward of any, he dealt with casualties under constant fire. His cheerfulness and confidence were an inspiring example to all.

Bar to the Distinguished Service Cross.

Surgeon ALFRED ROBINSON MACMULLIN, D.S.C., R.N.—For services with the 63rd (Royal Naval) Division in France. He worked unceasingly day and night for three days to succour the wounded. Times without number, when the enemy shelling and machine-gun fire was at its worst, he walked about in the most exposed places attending to the wounded, being utterly indifferent to his own safety. The result was that the lives of many men were saved who might otherwise have been blown to pieces where they lay. Throughout the whole of the operations his unflinching bravery won the admiration of all who saw him.

THE CONTRIBUTIONS TO RED CROSS.

M. Cambon, the French Ambassador, gave his support last week to the continued claim of the Red Cross upon the generosity of the nation. The occasion was the handing over to the French Red Cross by the Lord Mayor of London of a cheque for £355,530 collected on "France's Day." The most difficult time in France, M. Cambon said, will be after the conclusion of peace, because there will then be a very expensive liquidation. Crowds of repatriated men, mutilated and invalid, will return from Germany, and France will have to care for a great number of cripples, of blind men, and of needy people of every kind. M. Cambon welcomed the comradeship of charity which has been established between the women of France and of England, and drew a picture of women in their homes teaching French children to love England and English children to love France.

MEDICAL DEMOBILISATION.

Many of the surgeons in the Royal Naval Volunteer Reserve and medical officers of the Special Reserve and Territorial Forces have served away from the area of their practices since the beginning of the war, and the Central Medical War Committee has made a recommendation that all such who were engaged in private practice at the time of mobilisation should be released before other medical officers serving temporarily with the Forces. A resolution to this effect has been forwarded to the Ministry of National Service for transmission to the Interdepartmental Committee on Demobilisation, the Ministry itself endorsing the principle. Further, the Army Medical Department has agreed that Territorial and Special Reserve medical officers who have served since the beginning of the war should be released first from the Army, and that temporarily commissioned R.A.M.C. officers who have served longest should have the first claim for early repatriation, while those who have qualified since the war should be withdrawn from the Army last.

URBAN VITAL STATISTICS.

(Week ended Nov. 9th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had increased from 11·4 to 43·0 in the six preceding weeks, further rose to 43·8 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 55·5 per 1000, and coincided with that recorded in the previous week; among the remaining towns the rates ranged from 15·7 in Carlisle, 16·2 in Exeter, and 16·3 in Rochdale, to 63·8 in Swindon, 65·8 in Cambridge, 71·0 in Gillingham, 74·6 in West Ham, and 75·9 in Sheffield. The principal epidemic diseases caused 198 deaths, which corresponded to an annual rate of 0·6 per 1000, and included 57 from diphtheria, 52 from infantile diarrhœa, 35 from measles, 32 from whooping-cough, 16 from scarlet fever, and 6 from enteric fever. The deaths from influenza numbered 7560 or 148 above those recorded in the previous week, and included 2433 in London, 402 in Sheffield, 247 in Leeds 223 in West Ham, 187 in Birmingham, 186 in Bristol, and 168 in Hull. The 1197 cases of scarlet fever and 1155 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 4 and 11 below the respective numbers remaining at the end of the previous week. The causes of 75 deaths in the 96 towns were uncertified, of which 10 were registered in Birmingham and in Liverpool, 7 in Nottingham, 5 in Stoke-on-Trent, and 4 in London.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had increased from 10·6 to 30·5 in the eight preceding weeks, fell to 27·0 per 1000. Of the 1244 deaths from all causes, 87 were classified to influenza, which was also stated as a contributory cause in 447 deaths classified to other diseases; in the previous week these numbers were 66 and 493 respectively. The 410 deaths in Glasgow corresponded to an annual rate of 19·2 per 1000, and included 4 from diphtheria, 3 from whooping-cough, and 1 each from enteric fever and infantile diarrhœa. The 235 deaths in Edinburgh were equal to a rate of 46·2 per 1000, and included 2 each from scarlet fever and infantile diarrhœa, and 1 from whooping-cough.

Irish Towns.—The 459 deaths in Dublin corresponded to an annual rate of 60·0, or 5·5 per 1000 below that recorded in the previous week, and included 204 from influenza, 5 from infantile diarrhœa, 3 from diphtheria, and 1 each from scarlet fever and whooping-cough. The 256 deaths in Belfast were equal to a rate of 34·0 per 1000, and included 2 from infantile diarrhœa.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—M. Girgis (Sect. I.), Univ. Coll. Hosp.; O. Halstead (Sects. I. and II.), Guy's Hosp.; W. H. Haupt (Sect. II.), George Washington Univ.; D. Menzies (Sect. I.), St. Mary's Hosp.; G. E. Spero (Sect. I.), London Hosp.; and T. C. Stephen (Sects. I. and II.), Manchester.

Medicine.—M. Ibrahim (Sect. I.), Middlesex Hosp.; and T. A. Jordan (Sect. I.), Manchester.

Forensic Medicine.—C. R. Corfield, Manchester; I. R. Florence, Guy's Hosp.; H. B. Hyde, Middlesex Hosp.; G. F. Smith and T. C. Stephen, Manchester; and J. L. Walker, Glasgow and Univ. Coll. Hosp.

Midwifery.—G. M. Beaven, St. George's Hosp.; C. R. Corfield, Manchester; H. D. L. Jones, St. Mary's Hosp.; and S. H. Robinson, Guy's Hosp.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: O. Halstead, W. H. Haupt, and T. C. Stephen.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next quarterly meeting of the association will take place on Tuesday, Nov. 26th, at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Dr. John Keay, at 2.45 P.M. Dr. David Orr and Dr. R. G. Rows will contribute a paper (illustrated by lantern) entitled "The Interdependence of the Sympathetic and Central Nervous Systems."

INFLUENZA IN IRELAND.—Our Dublin Correspondent writes: Like other large cities in the kingdom, Dublin has suffered heavily from influenza. For several weeks physicians and general practitioners have been overwhelmed with work, and many among them have suffered in their own persons, although up to the present only one member of the profession in Dublin, Mr. J. H. R. Holtby, chief demonstrator of anatomy in Trinity College, has lost his life. The labours of medical men were rendered much heavier by the present shortage of nurses. Fortunately, the past 10 days show a great decrease in the number of cases, and few fresh cases are now occurring. The entire mortality of the disease appears to have been due to broncho-pneumonic complications. In the week ending Nov. 2nd 501 deaths were registered as occurring in the Dublin registration area. This represented an annual rate of mortality of 65·5 per 1000 of the population. The annual death-rate for the 44 weeks ending Nov. 2nd was 22·3 per 1000. Of the 501 deaths, 250 were registered as due to influenza and 89 to pneumonia. It is probable that the great majority of cases of pneumonia occurred in patients suffering from influenza. Our Belfast Correspondent writes: The influenza epidemic, after prevailing for about five weeks, is now very extensive in Belfast. Unlike the June visitation, which spread upwards socially from the workers, the present scourge attacked the better classes first, but has rapidly spread to all sections of the people, being in type, as a rule, mild, but with many deaths due to so-called pneumonia complications, which on post-mortem examination show the lungs filled with a hæmorrhagic exudate full of streptococci. The public health authorities have at last awoke (Nov. 7th), but their action is hopelessly belated. Indeed, the present situation would make thinking people very cynical were it not for the Hibernian sense of humour. Pasted in the windows of the tramcars is a public notice issued by the health committee, in which they "recommend all schools (both Sunday and day schools) and places of public entertainment be closed for at least ten days." As a result some of these places obey, others refuse; indeed, one of the kinema managers, in refusing to close, announced in one of the Belfast papers his willingness to show on the screen remedies for the influenza, and gave one—"phenol"—as a "sure and certain cure," by the use of which, he wrote, his employees were immune. Some of the schools have closed, others are still open, the education authorities concerned believing that to call on them to close these institutions while all places of amusement are allowed to be filled as usual is little short of a farce, and the public health authorities, it is reported, have no compulsory powers. The following precaution (suggested by the public health committee)—"avoid all crowded gatherings"—appears in the tramcars, but can only be read when these thronged methods of conveyance are free of the central strap-hangers. The public are becoming quite panicky, some calling out for injections of vaccine and others using remedies of which among the working classes the following is said to be the most popular: "24 drops of phenol to 8 ounces of water, two teaspoonfuls of the dilution being a dose." What amount of scheduled poison may thus be taken? Possibly an amount which in some people would cause carboluria. To crown all, owing to a strike of labourers in the house- and street-cleansing departments of the town council, the streets and back-yards of a great city with a population of 400,000 people have been left derelict for almost five weeks, so that from a sanitary point of view there is not at the present moment a more actually filthy city than Belfast. Everyone dreads—as a result—another epidemic which may be even worse than the influenza, though as I write (Nov. 12th) the strike has ceased.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Lieutenants to be Surgeon Lieutenant-Commanders: S. W. Grimwade, B. Taylor, H. H. Ormsby, E. Moxon-Browne, and A. E. P. Cheesman (acting Surgeon Lieutenant-Commanders), H. E. Perkins, E. C. Holtom, C. F. Willes, J. G. Danson, G. J. Carr.

ARMY MEDICAL SERVICE.

Col. Sir William B. Leishman to be Major-General, vice Major-Gen. Sir W. G. A. Bedford, retired.

Col. R. H. Luce (T.F. Res.) to be temporary Major-General.

ROYAL ARMY MEDICAL CORPS.

Temp. Major W. Murray (Lieutenant-Colonel, R.F.A., T.F.) to be temporary Lieutenant-Colonel.

Majors relinquishing the acting rank of Lieutenant-Colonel on re-posting: T. B. Moriarty, C. G. Browne.

To be acting Lieutenant-Colonels:—Whilst employed as Assistant Directors of Medical Services: Major (Bt. Lieut.-Col.) H. V. Bagshawe; Temp. Capt. W. Angus. Whilst in command of Medical Units: Majors G. De la Cour, J. J. O'Keeffe, A. W. Gater; Capts. A. C. Elliott, J. F. Grant, S. J. Higgins, E. A. Strachan.

Temp. Capt. W. Edmondson to be acting Major whilst specially employed.

To be temporary Majors: Temp. Major W. F. L. A. Holcroft (from South African Medical Corps) and Major R. S. White (from North Rhodesian Medical Corps).

Captains relinquishing the acting rank of Major on re-posting: T. J. Kelly and W. F. Christie.

Temp. Capts. C. L. T. Arthur and H. T. H. Butt relinquish the acting rank of Major.

To be acting Majors: Capts. P. A. Opie, F. P. Rankin, H. W. Carson, T. F. Kennedy, H. P. Rudolf, J. P. Litt, C. K. G. Dick, D. W. Pailthorpe, and H. Bedingfield; Temp. Capts. P. McCool (while specially employed), G. D. Laing, K. C. Middlemiss, A. E. Quine, R. B. Roe, W. W. Forbes, G. F. Bird, J. S. Stewart, A. Ryland, and A. B. Cardew; Temp. Lieut. T. E. Coulson.

The undermentioned temporary Lieutenants to be temporary Captains: F. W. Maunsell, W. Dalgliesh, C. H. A. Alderton, J. Robertson, W. O. Pitt, J. B. Burt, R. E. Moyes, H. Walker, V. T. P. Webster, J. J. Smith, M. J. Landy, J. M. Sheridan, W. T. Thomson, F. J. Cutler, I. Feldman, W. Murray, E. Clarke, W. H. Richardson, E. A. Miller, J. McCausland, H. M. Gilbertson, A. Evans, F. W. K. Lawrie, W. S. Gibson, T. C. Graves, H. Love, W. H. Condell, H. F. Penman, W. H. Ogilvie, G. Hoffmann.

To be temporary Captains: Capts. T. S. Keith (from Royal West Surrey Regiment, T.F.), A. Wallrugh (South African Medical Corps), J. Humphreys, C. W. J. Dunlop, T. Sheehan, A. E. Gravelle, C. V. Cornish.

To be temporary Honorary Captains: D. R. W. Crile, J. S. Burn (whilst employed with St. John Ambulance Brigade Hospital).

To be temporary Lieutenants: G. S. Livingston, W. J. G. Johnson, T. W. Lumsden, S. A. Bontor, H. G. Watters, R. Harley, H. H. McClelland, W. J. N. Todd, A. Linn, M. Rust, S. J. Healy, P. Carroll, G. A. Valentine, M. Cahill, J. N. McTurk, C. A. D. Bryan, J. Moulton, W. H. M. Smith, C. B. Gervis, G. A. Fothergill, R. J. Smith, T. T. Smith, J. D. E. Williams, A. Shearer, A. E. Ainscow, H. H. Patrick, S. T. Rowling, W. U. Morton, B. Dunlop, D. A. Johnstone, F. Anderson, D. M. Barcroft.

To be temporary Honorary Lieutenants: C. H. Backus, A. H. Miller (whilst serving with Welsh Hospital, Netley).

Officers relinquishing their commissions: Temp. Major A. M. Leake, V.C.; Temp. Capts. (acting Major) C. Roche (on account of ill-health contracted on active service, granted honorary rank of Captain), L. G. White (on account of ill-health, granted honorary rank of Captain); Temp. Capts. M. J. Mulligan and W. H. Howat (on account of ill-health contracted on active service, and are granted the honorary rank of Captain), H. A. Cecil (on account of ill health, and is granted the honorary rank of Lieutenant); Temp. Hon. Capt. A. Renshaw (on ceasing to be employed with Welsh Hospital, Netley); Temp. Lieut. H. N. Marrett.

Canadian Army Medical Corps.

Temp. Major J. S. Carruthers to be temporary Lieutenant-Colonel.

Temporary Captains to be temporary Majors: T. L. Towers, H. W. Whytock, (acting Major) J. R. Goodall, G. E. McCartney, (acting Major) H. J. Williamson.

Temp. Capt. R. N. W. Shillington to be acting Major while specially employed in a Hospital Ship.

Temp. Capt. W. A. Wilson to be acting Major while specially employed at a General Hospital.

Temp. Capt. (acting Major) C. F. Martin to be acting Lieutenant-Colonel while specially employed as Officer in Charge of a Medical Division.

Hon. Capt. H. J. Testar to be Honorary Captain, with pay and allowances.

ROYAL AIR FORCE.

Medical Branch.—F. F. Muecke (temporary Major, R.A.M.C.) is granted a temporary commission as Major and to be acting Lieutenant-Colonel whilst employed as Lieutenant-Colonel. The undermentioned are granted temporary commissions as Captains: G. C. Hall (Surgeon-Captain, retired, I.M.S.) and R. J. Aherne (late temporary Captain, R.A.M.C.). E. T. McElligott and W. C. A. Ovey are granted temporary commissions as Lieutenants.

Dental Branch.—The undermentioned are granted temporary commissions as Lieutenants: W. J. Singleton, J. Smith.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Parliament and the Armistice.

THE Prime Minister on Monday, Nov. 11th, read to the House of Commons the Armistice terms which the German delegates had signed that morning. The House adjourned immediately thereafter to a service of thanksgiving at St. Margaret's Church.

Ministries of Health Bill.

This measure was introduced by Dr. ADDISON, the Minister of Reconstruction, under what in Parliamentary procedure is known as the "ten minutes' rule." Ten minutes are allotted to the Minister for his introductory speech, and only one speech, similarly limited in time, is allowed of comment. Several Members rose to speak, but only one of them, Mr. HOGGE, had the opportunity of offering remarks on the measure. The Bill was formally read a first time, but there are now two motions for the rejection of the Bill on second reading. One stands in the name of Mr. HOGGE, the other in the name of Sir EDWARD CARSON. The motion of the latter is in the following terms:—

"That this House declines to proceed with a measure dealing with public health which excludes Ireland from the benefit of its provisions."

It is now announced that the Ministries of Health Bill will not be proceeded with this session. The text of the measure, however, is published.

Clause 1 sets out that for the purpose of promoting the health of the people throughout England and Wales, a Minister of Health may be appointed.

Clause 2 defines the general powers and duties of the Minister. It runs:—

It shall be the duty of the Minister to take all such steps as may be desirable to secure the effective carrying out and coördination of measures conducive to the health of the people, including measures for the prevention and cure of diseases, the treatment of physical and mental defects, the collection and preparation of information and statistics relating thereto, and the training of persons engaged in health services.

Clause 3 deals with the transfer of powers and duties to and from the Minister. It is as follows:—

(1) There shall be transferred to the Minister (*a*) all the powers and duties of the Local Government Board; (*b*) all the powers and duties of the Insurance Commissioners and the Welsh Insurance Commissioners; (*c*) all the powers of the Board of Education with respect to attending to the health of expectant mothers and nursing mothers and of children who have not attained the age of 5 years and are not in attendance at schools recognised by the Board of Education; (*d*) all the powers of the Privy Council and of the Lord President of the Council under the Midwives Act, 1902; (*e*) such powers of supervising the administration of Part I. of the Children Act, 1908 (which relates to infant life protection) as have heretofore been exercised by the Secretary of State.

It is, however, provided that the power conferred on the Insurance Commissioners of retaining and applying for the purposes of research sums mentioned in the Insurance Act shall not be transferred to the Minister, but the duties performed by the Medical Research Committee shall be carried on under the direction of a Committee of the Privy Council. The clause proceeds:—

(2) It shall be lawful for His Majesty from time to time by Order in Council to transfer to the Minister: (*a*) all or any of the powers and duties of the Board of Education with respect to the medical inspection and treatment of children and young persons; (*b*) all or any of the powers and duties of the Minister of Pensions with respect to the health of disabled officers and men after they have left the service, (*c*) all or any of the powers and duties of the Secretary of State under the Lunacy Acts 1890 to 1911, and the Mental Deficiency Act 1913.

Power is taken to transfer to other Government departments certain subjects such as public libraries, museums, and gymnasiums, fire brigades, and other matters now under the administrative supervision of the Local Government Board.

Clause 4, which authorised consultative councils, is to the following effect:—

(1) It shall be lawful for His Majesty by Order in Council to establish consultative councils for giving in accordance with the provisions of the Order advice and assistance in connexion with such matters affecting or incidental to the health of the people as may be referred to in such Order. (2) Every such council shall include persons of both sexes, and shall consist of persons having practical experience of the matters referred to the Council.

Powers are taken to carry out from an office in Wales the powers and duties transferred from the Welsh Insurance Commissioners.

Clause 9 constitutes a Scottish Board of Health which shall take up in Scotland the duties which in England and Wales fall on the Minister of Health. It will consist of not more than six members, one of whom must be a medical man holding a Public Health Diploma. The Board will act under the directions of the Secretary for Scotland. The clause contemplates the appointment of a Scottish Parliamentary Under-Secretary.

Under Clause 10 the National Health Insurance Joint Committee shall consist of the Minister of Health, who shall be chairman, the Secretary for Scotland, and the Chief Secretary for Ireland, together with one other person appointed by the Minister, being a person having special knowledge and experience of national health insurance in Wales.

There are other provisions of the nature of machinery in the Bill.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 6TH.

Influenza Epidemic at the Crystal Palace.

Answering Mr. CHANCELLOR, Mr. MACNAMARA (Secretary to the Admiralty) said: Since the present influenza epidemic broke out there have been 784 cases at the Crystal Palace; 538 were treated at the Palace, 233 were transferred from the Palace to local hospitals, and none were sent home for treatment. I should add, however, that 442 cases have been reported to us of men contracting influenza at home while on leave. As regards the number of deaths during the present epidemic, 3 died at the Crystal Palace, 93 died in local hospitals, and 10 died at their own homes.

Influenza at Blandford Camp.

In reply to Mr. W. ANDERSON and Sir G. GREENWOOD, who asked for information regarding Blandford Camp Major BAIRD (Under Secretary to the Air Ministry), said: The conditions at Blandford Camp have been receiving the close attention of the Air Council. Personal inspections have been made by Sir Humphry Rolleston, a member of the Medical Administrative Committee, by the inspector of hospitals, and by the medical administrator. Additional doctors and nurses have been sent there, the hospital accommodation has been materially extended, and the camp has been kept well supplied with all necessary medical stores and equipment. The total number of men who now are or have been stationed at Blandford from Sept. 21st to Nov. 2nd, 1918, is 32,593. The total number of deaths has been 78. Of these 77 were due to influenza or pneumonia consequent on influenza. The percentage of deaths is therefore 0·24 per cent. and the weekly average 13·5. The average daily number of men under canvas for this period has been 6611. The number has been steadily reduced, and it is hoped that all the men will be in buildings by to-night. From now on no recruits will be put under canvas.

Local Government Board and Medical Research.

Sir WILLIAM COLLINS asked the Parliamentary Secretary to the Local Government Board what was the total sum expended on auxiliary scientific investigations and medical research from the establishment of the Board to the present time.—Mr. S. WALSH replied: The grant for auxiliary scientific investigations concerning the causes and processes of disease was transferred from the vote for the Privy Council Office, to that of the Local Government Board in the year 1877–78. From that year to the present date sums amounting to £77,258 18*s.* have been paid for those investigations. In addition sums amounting to £15,361 3*s.* 3*d.* have been expended by the Board in respect of their pathological laboratory which was established in 1910.

THURSDAY, NOV. 7TH.

R.A.M.C. Officers in Ireland.

Answering Mr. LARDNER, Mr. MACPHERSON (Under-Secretary for War) said: A small number of officers of the Royal Army Medical Corps with recruiting experience have been employed in Ireland to assist the National Service Board. These officers are liable for service abroad if physically fit.

Dental Treatment of Discharged Soldiers.

Mr. PENNEFATHER asked the Financial Secretary to the War Office whether he would consider the advisability of so extending Army Council Instruction 1187 of 1918 as to include provision, if desired, for dental treatment prior to discharge of all soldiers returning from abroad whose teeth had deteriorated during their period of active service, and also to provide for the dental treatment, if desired, of all returned prisoners of war whose teeth had deteriorated during captivity.—Mr. FORSTER answered: This suggestion is not free from difficulty, but I will consider the question.

Medical Research Committee.

In reply to Sir WILLIAM COLLINS, Sir E. CORNWALL (representing the National Insurance Commissioners) wrote: The total sum expended up to the present time under my sanction and that of my predecessors under the National Insurance Act, 1911, by the Medical Research Committee has amounted to about £247,000.

Ministries of Health Bill.

Dr. ADDISON (Minister of Reconstruction) moved for leave "to bring in a Bill to establish a Ministry of Health and a Board of Health to exercise in England and Wales and in Scotland respectively powers with respect to health and local government and for purposes connected therewith."

He said: The war has revealed in a very striking manner what a good many of us have been calling attention to for many years—namely, the need for improvement in the health of our people. After the war the need will be greater almost than during the war for making the best use of all our powers and resources, and it is very certain that in the time of reconstruction we shall not be able to afford any waste either of material or of human power. The late Lord Rhondda, when he was President of the Local Government Board, invited me to take charge of an inquiry into this matter, and during recent months I have had very many consultations with the local authorities of this country, with medical men, and with representatives of the great insurance organisations, and the measure which I ask leave to introduce represents, except in some unimportant particulars, a common measure of agreement.

Mr. BOOTH: No.

Dr. ADDISON: The honourable Member not having seen the measure is not in a position to say. There is unanimity on the part of all who have examined this topic that steps are necessary and that it is impossible in this country either to prosecute a vigorous health policy or to secure efficient administration of it until we have brought about in the first place the consolidation of those Government authorities who have charge of it. For example, with respect to woman and her child, the Local Government Board, the Insurance Commission, the Home Office, and the Privy Council are all involved in various matters concerning the health of the mother and her child. I could, of course, furnish many illustrations, but it is obvious to anyone who has knowledge of public administration in this country that it is impossible to expect any progressive and continuous development of improved service while you have this overlapping in the central departments, and the main purpose of the Bill is to bring together, under one body of men and one Minister, the chief Government departments concerned in matters affecting the health of the people. Until that is achieved I am convinced that it is hopeless to expect any real and substantial improvement. This Bill does not provide medical treatment for any individual. It does not affect the functions of any local authority of any kind. It is purely concerned with bringing together the responsibilities of the different Government departments, both in England and in Scotland, which are concerned with health matters. The Bill brings together under one Minister the powers and duties of the President of the Local Government Board and the Health Insurance Commission of England and Wales. It brings in also the powers and duties of the President of the Board of Education with regard to the health of mothers and infants, the duties of the President of the Council with regard to midwives, and the Home Secretary with regard to the protection of infant life.

Sir E. CARSON: Does the Bill apply to Ireland?

Dr. ADDISON: I will deal with that presently. It unites those in one health department and then we take power in the Bill to bring in, as and when it is possible, other considerable health duties—namely, the medical inspection and treatment of school children, at the present time under the charge of the Board of Education. Further, all the health duties of the Ministry of Pensions as regards the treatment of sick soldiers and, finally, the powers of the Secretary of State for the Home Department with regard to lunacy and mental deficiency. It is not proposed to consolidate these latter powers at this stage. They are involved in various administrative arrangements which it would take some years at least to disentangle. A good deal of misapprehension exists with respect to this Bill owing, perhaps, to the fact that we have not been able to bring it forward earlier in consequence of the association of these health services with the present Poor-law duties discharged by boards of guardians who are responsible to the Local Government Board. I may say that the bringing together of the different services which I have mentioned in no way fixes to these services any Poor-law taint whatever. It is separate from them hereafter as it is now, for example, from the sanitary services of the local authorities. We have had an important committee presided over by the Deputy Chairman of Ways and Means, and I am authorised to say that the report of the Local Government Committee presided over by Sir Donald Maclean on the transfer of the functions of Poor-law authorities in England and Wales has been carefully considered by the Government, and that the Government accepts the recommendations of the committee that all services relating to the care and treatment of the sick and infirm should not be administered as part of the Poor-law, but should be made a part of the general health services of the country, and that the Government regards it as a matter of urgency that effect should be given to these recommendations as soon as possible. The Government accepts the principle that the remaining functions of the Poor-law authorities should be transferred to other bodies, but are not in a position to formulate precise proposals at the present time. Any approach to the complete application of the scheme recommended by the committee will involve a considerable length of time, and must be preceded by further inquiries into certain questions with regard to detailed matters. The Government recognises its responsibilities for making proposals on these subjects as soon as the exigencies of the Parliamentary situation permit of their doing so. I should like to say here that those enthusiasts for a Health Ministry who say we must wait until we have reformed the Poor-law are thoroughly impracticable people. The Poor-law will require many years of steady effort, both in this House and in connexion with administration, wholly to disentangle and to bring about the reforms which many of us desire, but we are not prepared to postpone until that is achieved the necessary consolidation of these important health services. With regard to Scotland, the Bill brings together in precisely the same way as in England these different health services under a board—a Board of Health—which is responsible to the Secretary for Scotland, who has had charge of this part of the Bill in the course of its formation. With regard to Ireland, we have not extended our proposals therein view of the possibility, as we hope soon, that Ireland may administer her affairs herself. But it is proposed to leave the position of the Irish Insurance Commissioners as far as possible unchanged. We do provide, however, for the continuance of the Joint Committee similar to that which is now in existence representing the four countries with regard to financial matters.

Sir E. CARSON: Is that all there is about Ireland in the Bill?

Dr. ADDISON: Another important feature of the Bill is that we provide advisory or consultative councils as part of machinery of the Ministry. This proposal has been a good deal criticised in many quarters, and I for one thoroughly believe in having at my elbow expert critics. I believe it will have a very wholesome effect on administrative work, certainly in the development of the health services of this country, if we have a live active body of this kind in existence.

Mr. CHANCELLOR: Are they to be empowered to go over the heads of the Ministry?

Dr. ADDISON: Certainly not. The Ministry must be responsible. In order that it may be made clear what the functions of these advisory councils are I propose to lay on the table of the House a draft Order in Council, which sets out their functions and which has been agreed to by all concerned. They deal with matters referred to the Ministry. They are to be able to make suggestions to the Ministry on subjects that may be referred to. They are also on their own initiative to make recommendations. We bring together, therefore, under this Bill all the important Government services which are concerned with health, and we thereby also bring under one Ministry the surveillance of all the local health services of the country. If this is achieved we believe that it will be possible to expect real progress with respect to the improvement in the health of the people. It is essential to take this step first because the legislation necessary to provide for the full development of the health services of the country may be controversial and certainly will be difficult and involved. Therefore it is necessary to take it in two stages. I believe that if we acquire the powers sought in this Bill we may for the first time in this country be able to develop and ultimately to apply scientific, well-thought-out and thorough health measures for the benefit of our people.

Mr. HOGGE gave certain reasons why he opposed the introduction of the Bill. In the first place, it attempted to take away from the National Health Insurance Commissioners in three parts of the kingdom their existing rights to deal with questions of disease and ill-health. He also opposed the Bill because there was associated with it the administration of the Local Government Board, which administered the Poor-law. If the right honourable gentleman had acquainted himself with the views held by large bodies of Approved Societies in England, Wales, and Scotland with regard to the inclusion of the functions of the National Health Insurance under any Government department associated with the Poor-law, he would have known the strength of the opposition to it. He knew that the right honourable gentleman had not taken the trouble.

Dr. ADDISON: That is entirely incorrect. I have consulted scores of representatives of authorities and of Approved Societies.

Mr. HOGGE said that he knew that as far as the National Health Insurance Commissioners in Scotland were concerned, they had never been asked their views at all on the question of a Ministry of Health and how far their functions should be roped in under the new arrangement. Moreover, in Scotland there was a demand for a separate Bill dealing with a Ministry of Health for Scotland. In these declining days of Parliament it was absurd to bring in what was really an electioneering measure.

Leave was given, and Dr. ADDISON formally brought in the Bill. He intimated that it was "backed" by Sir George Cave (the Home Secretary), Sir Auckland Geddes (President

of the Local Government Board), Mr. Munro (Secretary for Scotland), and Sir E. Cornwall (the representative of the National Insurance Commissioners).

The Bill was read a first time.

TUESDAY, NOV. 12TH.

Medical Women and Army Service.

Answering Mr. W. THORNE regarding the suggestion to give commissions to medical women, Mr. MACPHERSON (Under Secretary for War) said: I am informed that even if the Government entertained the proposal there is no possibility of the necessary legislation being introduced this session.

WEDNESDAY, NOV. 13TH.

The Shortage of Medical Men.

Major EDWARD WOOD asked the Representative of the National Insurance Commissioners whether his attention had been called to the difficulty experienced by many persons in country districts owing to the shortage of medical officers during the present epidemic of influenza in securing the certificate of a medical officer necessary to obtain sick benefit under the National Insurance Act; and whether he could make provision by which money to which such persons were entitled might be more easily and expeditiously obtained.—Sir E. CORNWALL replied: I am aware of and am giving careful attention to the serious difficulties under which the medical profession are striving to carry out their duties just now with their numbers so depleted by the demands of the Army for medical men and the great aggravation of these difficulties by the present epidemic, and I trust that Approved Societies generally are showing all possible consideration for these conditions in their dealing with sickness benefit claims from their members. But I am advised that a general relaxation of the requirement of periodical medical certificates as evidence of incapacity for work would be open to grave objection as tending to destroy the administrative basis requisite for financial stability.

Replying to a supplementary question, Sir E. CORNWALL stated that negotiations were now being carried on with a view to bring home medical men to this country as rapidly as possible.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.
THURSDAY, Nov. 21st.—Papers:—Mr. W. Stiles and Dr. F. Kidd: (1) The Influence of External Concentration on the Position of the Equilibrium attained in the Intake of Salts by Plant Cells; (2) The Comparative Rate of Absorption of various Salts by Plant Tissue.—G. THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Dawley, Salop.

Births, Marriages, and Deaths.

BIRTHS.

KELLY.—On Oct. 31st, at The Orchard, Bushey Grove-road, Bushey, Herts, the wife of Lieutenant-Colonel W. D. C. Kelly, D.S.O., R.A.M.C., of a daughter.

LEE.—On Nov. 5th, at Prince's-gate, the wife of Captain Harry Lee, F.R.C.S., R.A.M.C. (T.F.), of a son.

PAYNE.—On Nov. 5th, at Glengarry, Park-hill, Ealing, W., the wife of Surgeon-Lieutenant R. W. Payne, R.N., of a daughter.

REYNELL.—On Nov. 6th, at Highweek, Newton Abbot, the wife of Captain R. W. Reynell, R.A.M.C., of a daughter.

MARRIAGES.

COLLET—TYDD.—On Nov. 6th, at All Saints' Church, Ascot, Lieutenant-Colonel G. G. Collet, R.A.M.C., to Gertrude Eulalie, daughter of Mr. and Mrs. George B. Tydd, of Burleigh Lodge, Ascot.

GREEN—GARLICK.—On Nov. 8th, at St. Saviour's Church, Eton-road, N.W., Philip Withers Green, Captain, R.A.M.C. (T.), to Florence Hester, eldest daughter of the late George Garlick, M.D., of Gordon-square, and Mrs. Garlick, of Steele's-road, Hampstead.

DEATHS.

DAWNAY.—On Nov. 8th, at Marchwood-crescent, Ealing, of pneumonia following influenza, Archibald Hugh Payan Dawnay, F.R.C.S.

DICKEY.—On Nov. 4th, at Oakham, J. S. P. Dickey, M.A. Oxon., M.B., Ch.B. Edin., in his 36th year.

FISHER.—On Nov. 6th, at King's Langley, Frederick Charles Fisher, F.R.C.S., aged 60.

LOGAN.—On Oct. 31st, at Stone, Aylesbury, from influenza, Thomas Stratford Logan, L.R.C.P. & L.R.C.S. Edin., D.P.H. Lond., Assistant Medical Officer, Bucks County Asylum, elder son of the late William Logan, M.D., and of Mrs. Logan, Whitehead, co. Antrim.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

INFLUENZA DISINFECTION AND THE RÔLE OF THE CARRIER.

ON Nov. 6th, at the Royal Institute of Public Health, Professor J. M. Beattie delivered the fifth of a course of lectures on Public Health Problems Under War and After War Conditions. He began by referring to the work that had been done in regard to typhoid carriers. Many such were found among persons who showed no clinical symptoms of the disease. Cure was a difficult matter, and all workers recognised intermittent discharge at long intervals of pathogenic organisms in the fæces. Men were discharged as "cured" who still had bacteria in their urine. Such unsuspected carriers distributed among the population might become serious centres of infection. The same applied to the pneumococcus, the diphtheria bacillus, meningococcus, &c. An important matter seemed to the lecturer to have been neglected by sanitary authorities. In the act of flushing a water-closet spray is produced which may easily spread bacteria to the immediate surroundings, but in how many cities is the public closet disinfected after use? In the case of typhoid and dysentery carriers clothing and hands readily become infected and provide a fruitful source for the spread of disease. Infections of the upper air-passages are easily spread by the spray produced in coughing, more especially when overcrowding is also present, as was unavoidably the case in the present epidemic of influenza, where, owing to war conditions, a lowered resistance of the body was an added factor. Professor Beattie described a spray of electrolysed 3 per cent. saline solution to be used for disinfecting soldiers on a large scale. Although certain mechanical difficulties at present stand in the way of its use for the general public, an ordinary hand spray can be used. Disinfection of the throat is one of the most important factors, both in checking the carrier-rate and the actual spread of many common infections. It should be a routine practice in fever hospitals to disinfect the nose and naso-pharynx at least once every day, while in schools a daily nose and throat drill is to be desired. Children should thus learn that cleanliness of the mouth and upper air-passages is as important as that of hands, face, and teeth. In dysentery cases thorough washing out of the bowel is required. Cases of infantile and summer diarrhœa treated on these lines had produced striking results in the lecturer's hands. In the discussion which followed the lecture Professor J. R. Simpson urged that influenza should be made a notifiable disease, and Dr. T. N. Kelynack instanced an open-air sanatorium of 100 beds, not far from London, with visitors constantly coming and going, where no cases had occurred. The same was the case with a children's sanatorium, although cases had occurred among the outside staff, while another institution for children not far away, where open-air treatment was not in force, had had half its inmates in bed. Professor Beattie, in reply to questions, considered that influenza probably conferred a certain amount of immunity, but for a brief period only. Vaccine treatment, if practised at all, should, he thought, be on the lines suggested by the recent War Office conference (see THE LANCET, Oct. 26th, p. 565). Notification of influenza was a difficult task.

THE INSTITUTE OF HYGIENE.

THIS Institute proposes to build a Temple of Hygiene in the centre of London in order to provide better facilities for its work. Sir Malcolm Morris is acting as chairman of a committee to promote the scheme. Sir Samuel Scott, Bart., M.P., is the honorary treasurer.

THE LEBANON HOSPITAL FOR MENTAL DISEASES.

DURING the four years of war the Lebanon Hospital for Mental Diseases, near Beyrout, founded in 1896 by the late Theophilus Waldmeier, has been allowed to carry on its beneficent work without cessation under the care of the British director, Dr. H. Watson Smith. The work of the hospital has necessarily had no publicity given to it during recent times, and this has made it a difficult matter to keep up the necessary remittances for its maintenance. This has been done, however, through the kind offices of America. The Turks at one time desired to commandeer the institution for military purposes, but found that it was doing such good work amongst people of all races and creeds that they decided to leave it, and Djemal Pasha even presented 100 sacks of wheat at a time of difficulty.

The way is now clear and money can be sent through to Beyrout. The hospital needs help badly; food and other necessaries have been, and are, very expensive; added to this, when details are received it will be found that repairs are needed after the four years of war conditions. The difficulties have been many and formidable, but Dr. Watson Smith and his helpers have been able in a wonderful way to "carry on." The committee appeals for wider interest and for financial help to bring the hospital, which is the only one of its kind in the country, fully up to date. Information will be given by the general secretary, Lebanon Hospital Office, 35, Queen Victoria-street, London, E.C. 4.

THE MEDICAL MAN'S INCOME TAX.

To the Editor of THE LANCET.

SIR,—In the article by Mr. John Burns on the above subject, published in your columns of Oct. 19th, it is stated, with reference to taxable income, that the deductions permissible include "professional subscriptions and literature." I have inquired of the Surveyor of Taxes whether a subscription of 3 guineas to the Royal Society of Medicine and 30s. to THE LANCET may be deducted, and have received the following reply:—

"In reply to your letter of the 28th inst., I beg to inform you that subscriptions to medical societies are not admissible deductions for income tax purposes.

With regard to your claim to deduct the cost of literature, the matter appears to be governed by the case of Charlton *v.* Commissioners of Inland Revenue, 1890, 17 R. 785, in which it was decided that a minister assessed under Schedule E. was not entitled to a deduction in respect of cost of books purchased in connexion with his profession."

I enclose my card.—I am, Sir, yours faithfully,
Nov. 5th, 1918. MEDICAL SUPERINTENDENT.

*** Income-tax interpretation is not an exact science, and its practical application varies in different parts of the country. Whilst the purchase of a professional library would not be permitted as a legitimate deduction, replacements are generally allowable, and should be claimed. Subscriptions to medical societies should also be claimed, despite the opinion expressed in the letter of the Surveyor of Taxes above.—ED. L.

Introductory Remarks ON EPIDEMIC CATARRHS AND INFLUENZA.

Delivered at the Discussion on Influenza at the Royal Society of Medicine, Nov. 13th, 1918,

BY SIR ARTHUR NEWSHOLME, M.D., K.C.B.,
MEDICAL OFFICER TO THE LOCAL GOVERNMENT BOARD.

MR. PRESIDENT AND GENTLEMEN,—When I promised to open this discussion it could not be forecasted that we were about to experience our national share of a pandemic of influenza unexampled both in distribution and severity. Under present circumstances a discussion on influenza will necessarily include consideration, so far as our lack of knowledge will permit, of the circumstances leading to the minor epidemics with which in recent years we have been fairly familiar, and those leading to the mysterious occurrence of the wider pandemics, such as those of 1890 and of the present year.

It is necessary, in my view, to consider these minor epidemics and the endemic prevalence of influenza in this country in relation to bronchitis and pneumonia, which year by year cause a much heavier toll on health and life than is demanded by influenza. I have little hope of success of any personal or public measures against influenza which will not influence even more favourably the incidence of bronchitis and pneumonia. It is not improbable, in fact, that the influenza problem may be most successfully attacked when influenza is not epidemically prevalent.

ETIOLOGY.

The first difficulty is to define influenza. Is it one disease, or a group of diseases? And is the disease now prevailing the disease which prevailed in the spring, and still more in July, of this year? These two questions cannot easily be separated. The symptoms were usually milder in the earlier than in the present outbreak, but that may be due to the very exceptional culmination of the epidemic in the summer months. War conditions prevented civilian bacteriological work on the disease on a considerable scale, but I am hoping that this discussion will elicit contributions as to the bacteriology of the July and the present outbreak, and that later the results will be available of the inquiries by the Medical Research Committee, who have been collating evidence from military as well as civilian outbreaks, and making independent inquiries.

The report of the Influenza Committee of the Advisory Board to the D.G., Medical Department, France,[1] shows that influenza has occurred at intervals among our forces in France, and that a serious epidemic occurred in the spring of this year. The known facts bearing on the position of Pfeiffer's influenza bacillus as the cause of the epidemic are well summarised in this report. This bacillus cannot be said to have established its position, nor can it be disregarded; for even if some other organism be the essential virus of influenza, the Pfeiffer bacillus is probably one of the chief sources of the damaging complications of this disease.

From this country, from France, and from America there is evidence that occasionally influenza kills rapidly by toxæmia, but more often by pulmonary complications; and that in producing these complications hæmolytic streptococci have been predominating organisms, the Pfeiffer bacillus and the pneumococcus also being found in a varying proportion of cases. The increase in virulence in streptococci in animal passage is well known. There can be no doubt that all these bacteria, often acting in conspiracy, have contributed greatly to the recent mortality from influenza, but whether there is in addition a hitherto undiscovered virus to which influenza is primarily due is still a moot point.

The occurrence of such mixed infections is well known in other diseases; it is a chief source of mortality in measles, and success in the sanatorium treatment of tuberculosis depends largely on the elimination of secondary infections; and this points to oral, naso-pharyngeal, and dental hygiene and life under improved sanitary conditions as at present among the most hopeful lines of action in diminishing the mortality from bronchitis, pneumonia, and influenza in the general population.

[1] Brit. Med. Jour., Nov. 9th, 1918.

INFLUENZA AS A CLINICAL ENTITY.

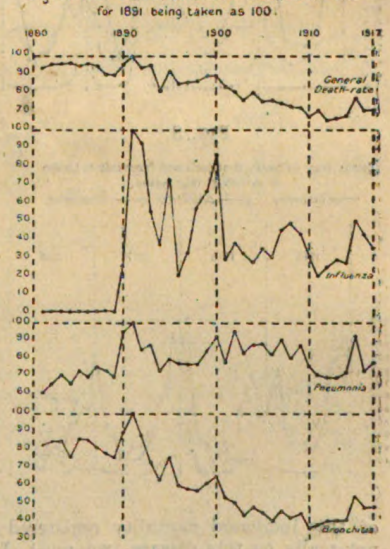
In view of the uncertainty in the bacteriological diagnosis of influenza, can this disease be recognised as a clinical entity? In typical cases it can, but certainly not in a very large proportion of atypical and modified attacks. In France, for instance, it has been found difficult to diagnose influenza from trench fever when the latter is unaccompanied by relapses. The main diagnostic evidence of the presence of influenza is its occurrence epidemically or pandemically. Diagnosis by this means is not helpful in prophylaxis, and there is the further possibility that other catarrhal infections may—though there is little evidence of this—take on transcontinental travels. This probably happens with the meningococcus, causing in most recipients little or no evidence of disease.

But the facts remain that influenza is a specific disease recognisable in severe outbreaks, and that it is a disease which, with the exception of plague and cholera, has on occasion travelled further and more rapidly over the world than any other recognised disease. It differs from these two diseases in that their pandemic course can be stayed by organised measures which are well within human capacity. I know of no public health measures which can resist the progress of pandemic influenza. It is noteworthy that the relative failures of preventive medicine and public health to secure control over disease have been concerned with diseases in which infection is received by the respiratory tract—especially influenza, bronchitis, pneumonia, measles, and whooping-cough.

DEATH-RATES FROM CHIEF CATARRHAL DISEASES.

We need further knowledge—epidemiological, pathological, and bacteriological—of all these diseases before they, and especially before influenza, can be brought within the scope of preventive medicine. Acute respiratory diseases, chiefly bronchitis and pneumonia, cause approximately one-sixth of the deaths from all causes; and this does not include the deaths in measles and whooping-cough chiefly caused by respiratory complications, and the deaths under the heading of other diseases in which respiratory complications turn the balance against recovery.

FIG. 1.



In Fig. 1 is shown the general course of the death-rate in this country since 1881 from the three chief fatal catarrhal diseases. The death-rates are given as relative figures, all the rates being reduced to the same magnitude so that a comparison may be made of the percentage variation under each heading.[2] The variations in the death-rate from influenza are evidently greater than those for pneumonia and bronchitis, though in nearly every instance they are in the same direction in any given year. The decline of the death-rate from bronchitis without corresponding increase of pneumonia points to the conclusion that much of the decline under the first heading is real and not due to changing fashion in certification.

In Figs. 2 and 3 this comparison between deaths in London from influenza, bronchitis, and pneumonia is pursued further,

[2] It should be noted that even in years in which influenza is epidemic bronchitis and pneumonia cause several times as many deaths as this disease. Probably many of these deaths are secondary to influenza.

the four-weekly incidence of mortality from each of these diseases being shown on the graph, for the four years 1889–92, in three of which influenza was epidemic, and for the four years 1915–18, in each of which some rise of the influenza curve occurred. In three of these last years the rise followed the almost universal rule of winter or spring incidence, the exception being the larger peak of July, 1918, and the still higher present peak. Several important points may be gathered from these graphs. Pneumonia and bronchitis nearly always have their maximum mortality in the winter months. In 1891 excessive mortality from both bronchitis and pneumonia was prolonged into the late spring, coincidently with a spring epidemic of influenza. In 1918 the summer outbreak of influenza was not associated with marked increase in the pneumonia death-rate, though it is likely that the excessive pneumonia mortality characterising the whole of 1917 and 1918 was associated with fairly widespread prevalence of influenza.

MORTALITY FROM INFLUENZA SINCE 1847.

The course of influenza in this country from 1847 can be gathered approximately from the annual death returns as displayed in Fig. 4. A preliminary remark is required. Our national death statistics are the least imperfect in the world; but the accuracy must always necessarily be limited by the extent to which medical certification of the cause of death is satisfactory. In the earlier epidemics of influenza, including the outbreaks of 1890–93, there is strong reason for concluding that deaths from influenza were certified under the heading of the pneumonia or bronchitis secondary to influenza in a much higher proportion than in recent years. This probability is increased by the large mass of endemic influenza revealed in Fig. 4 from 1890 onwards, but almost absent in earlier years. The difference in part is probably a real difference, though probably not entirely so. Although much of this increased mortality registered from influenza may not really be this disease, we must, I think, assume that conditions since 1890 have become more favourable than in earlier years for the continuous prevalence of influenza endemically on a considerable scale.

FIG. 2.

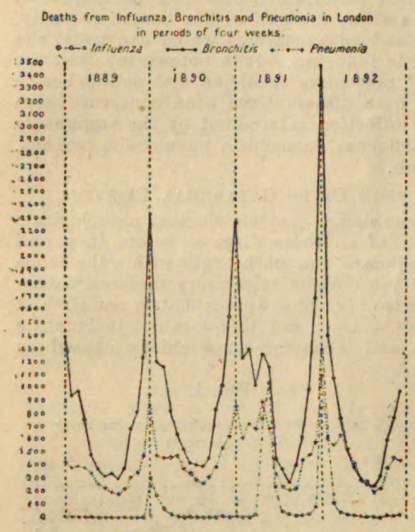


FIG. 3.

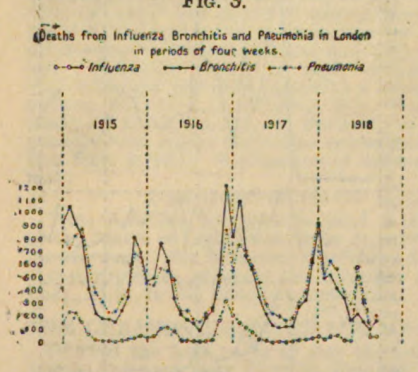
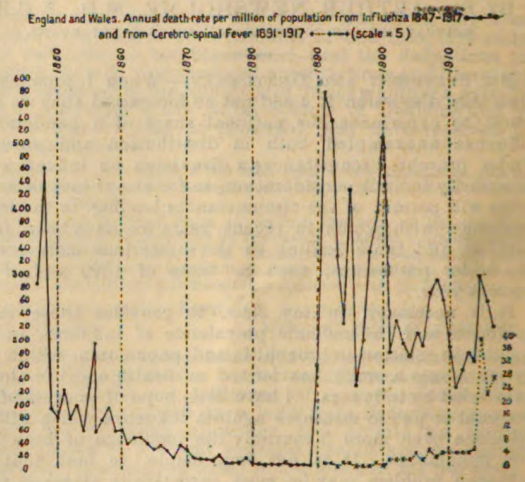


INFLUENZA, CEREBRO-SPINAL FEVER, AND PNEUMONIA.

I have introduced into Fig. 4 (scale five times that for influenza) a further curve showing the annual death-rate from cerebro-spinal fever since 1881. It is suggestive that this disease scarcely maintained a footing in England during 1881–1914, but since then has prevailed each winter epidemically, although each case as a rule occurred sporadically, in the sense of not being traceable to any other case of the same disease. This difference in the annual curves of influenza and cerebro-spinal fever does not appear to support the seductive hypothesis of Dr. Hamer that both these diseases may be diverse manifestations of the same virus.

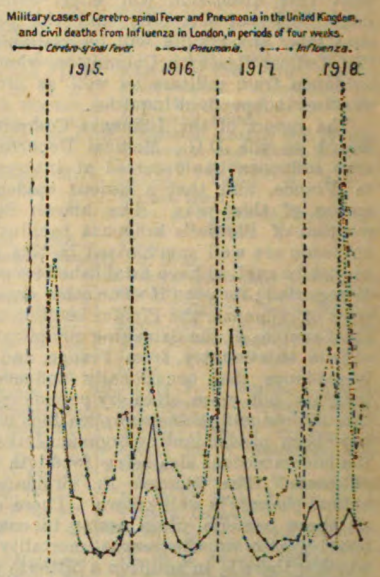
On the other hand, Fig. 5 may be examined. This gives a comparison between the four-weekly incidence of cases of cerebro-spinal fever and of pneumonia in the British Army in the United Kingdom during the four years 1915–18. This curve is introduced by permission of the Director-General of the Army Medical Department. The two diseases are plotted out on the same scale, the scale being omitted. The cases are enumerated as first notified without subsequent correction, but this does not detract materially from the general value of the curves for comparative purposes. On the same diagram I have plotted the number of deaths from influenza in four-weekly periods in London. The two sets of figures, although derived from different sources, may be regarded as roughly comparable.

FIG. 4.



There is shown a close correspondence in the curves of these three diseases during three out of the four years and there can be little doubt that the same winter and spring conditions favour excess under all three headings. The experience of 1918 is instructive. In this year influenza had an epidemic peak in July, and the deaths from pneumonia in the Army showed a corresponding peak. Cerebro-spinal fever, however, did not follow the two other diseases.

FIG. 5.



COURSE OF INFLUENZA MORTALITY IN LONDON.

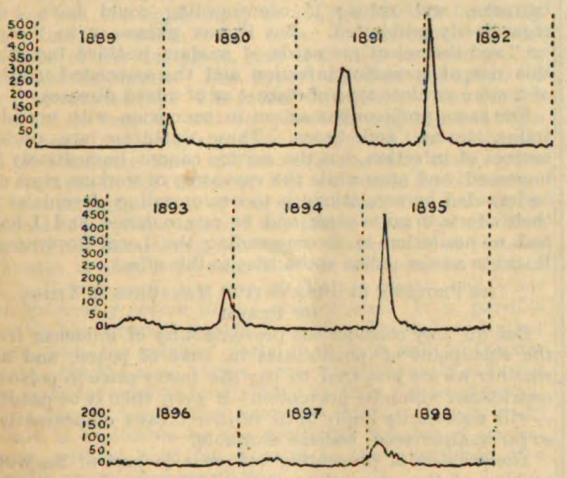
The course of influenza in this country from year to year has been shown in Figs. 1 and 4. Its weekly course, judged by weekly deaths from influenza registered in London, is shown in Fig. 6. Prior to 1890 deaths from influenza scarcely

figured in the death returns. From this year the course of events may be briefly summarised thus:—

1890.—An epidemic culminated in the third week of January. The epidemic peak occupied about five weeks, the excess of influenza gradually tailing off subsequently in this and in the later epidemics shown in Fig. 2. Between the peaks of this and of the next epidemic 70 weeks elapsed.

1891.—An epidemic occurred culminating in the twentieth week of the year. The epidemic peak occupied eight to ten weeks. Between the peaks of this and of the next epidemic 35 weeks elapsed.

FIG. 6 A.



1892.—An epidemic occurred culminating in the third week of January. The epidemic peak occupied six to eight weeks.

1893.—No great epidemic occurred, but some excess of mortality from influenza for several weeks in the early spring. A smart epidemic culminated in the fiftieth week of the year, the epidemic peak occupying about seven to nine weeks.

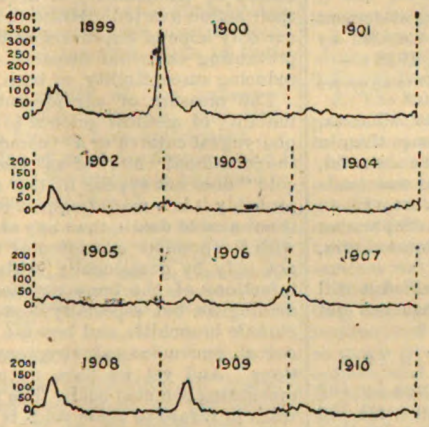
1894.—No epidemic, except the one beginning in 1893.

1895.—A large epidemic culminated in the tenth week of the year, the epidemic peak occupying 6–8 weeks.

1896.—No epidemic.

1897.—No considerable epidemic.

FIG. 6 B.



1898.—An epidemic occurred which reached its rather low maximum in the fifth week of the year. Its duration was somewhat protracted.

1899.—A somewhat similar epidemic to the one in 1898 culminated in the eleventh week of this year.

1900.—An epidemic occurred in December, 1899, and January, 1900, the greatest mortality occurring in the second week of January, 1900. The peak of this epidemic occupied six weeks, the mortality slowly tailing off. The interval between this and the preceding peak was 42 weeks.

1901.—No epidemic.

1902.—A small epidemic reaching its maximum in the eighth week of the year. The epidemic lasted six to eight weeks. An interval of over two years had elapsed between this and the last previous epidemic.

In 1903, 1904, and 1905 no epidemic of influenza occurred, though occasionally the weekly deaths from this disease rose slightly above the usual inter-epidemic level.

1906-7.—An epidemic occurred in December, 1906, and January, 1907, of low magnitude and somewhat protracted duration.

1908.—A smarter epidemic of influenza occurred, culminating in the ninth week of the year. Its duration was six to eight weeks, the tailing off commonly seen in other epidemics being shown in the curve.

1909.—An epidemic occurred with its maximum in the twelfth week of the year, similar in course and duration to the epidemic in 1908. The interval between these two epidemic peaks was 55 weeks.

1910, 1911, 1912.—No epidemics.

1913.—An epidemic of low range occurred with a maximum mortality in the twelfth week of the year.

1914.—No epidemic.

1915.—An epidemic similar to that of 1913 occurred, the low maximum being reached in the eighth week of the year.

1916–17.—A considerable low ranged increase of mortality was visible in the early part of 1916, followed by a relatively small epidemic, culminating in the last week of the year and terminating early in 1917.

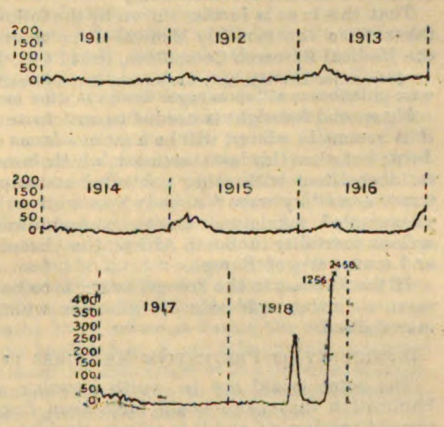
In the previous statement deaths only are dealt with, and I have selected the metropolis because for it we have an uninterrupted statement of weekly deaths from various causes for a long series of years. It will be noted, however, that London is a densely populated province, and that its epidemic curves represent the smoothed-out results of many local outbreaks which have rapidly become general.

The Pandemic in 1918.

Reference to Fig. 6 C shows that influenza during this year has followed a course never previously experienced. Until towards the end of June the London curve showed scant mortality from influenza, the number of weekly deaths between the eighteenth and twenty-fifth weeks varying from 5 to 10. There is evidence that prior to this influenza had been fairly widely prevalent, as it could not fail to be, inasmuch as during the spring of this year influenza prevailed seriously among both the Allied and enemy troops, and in Spain the epidemic of influenza had got well ahead in May. In July influenza was widely prevalent and was causing excessive mortality (see Fig. 5) not only in England, but also all over Europe, in the United States, in the great cities of India, and elsewhere.

I have not found another instance of a widespread epidemic culminating in the summer months (i.e., after June 22nd). The London curves, with this single exception, show that

FIG. 6 C.



since 1881 epidemic peaks have always occurred in winter or spring. Even in the epidemic culminating in July last streptococcal infection had been noted by various observers; and it is noteworthy that in American accounts of outbreaks of influenza in camps and in the civilian population of America during both 1917 and 1918 there were reports of this same preponderant occurrence of hæmolytic streptococci in the lesions and secretions. During the spring and throughout the summer of this year the usual endemic influenza probably was being almost constantly replenished by more virulent infection on a very large scale from overseas from both the American and European continents.

The further course of influenza in this year presents altogether exceptional, if not unique, features.

The curve shows clearly that in London after an epidemic causing excessive deaths during some six weeks in July and August—weekly deaths from influenza 10 (25th week), 67, 218, 287, 192, 86, 38 (31st week)—the weekly deaths declined, the deaths in each of the following weeks being 21, 20, 12, 12, 12, 14, 9, 17, 17.

In the 41st week occurred a sudden increase of deaths to 80, and then in following weeks the deaths numbered 371, 1256, 2458, and 2433.

Reference to Fig. 6 C shows that this experience, as already stated, is different from the experience in any preceding year.

The interval between the peak of the July epidemic of 1918 and of the smaller epidemic in 1916–17 was 80 weeks; the corresponding interval between the July and the October to November epidemic peaks in this year was about 16 weeks. This last-named interval is less than half of the interval elapsing between any two previous epidemic peaks of influenza in the metropolis, the nearest approach being 35 weeks' interval between the epidemic peaks of 1891 and of 1892.[3]

THE QUESTION OF A SECONDARY WAVE.

The Secretary of the Medical Research Committee in the *British Medical Journal* of August 10th, at the end of an annotation headed "Bacteriology of the Influenza Pandemic," asked bacteriologists in this country to send results of their observations during the epidemic—

"In order that the results gained here may be collected, with a view to the organisation of such coördinated work as may be found possible for the study of the secondary waves of infection that are to be expected."

This statement was, I fear, overlooked by many bacteriologists as it was by myself; otherwise many who did not know would, I am confident, have sent contributions for the common stock. But in some journals an attempt has been made to show on the strength of the above quotation that public health authorities, central and local, did not take all possible steps in anticipating and mitigating the present major epidemic of influenza.

Furthermore, in an answer to a Parliamentary question, the above cautious statement has been asserted to have included also a forecast that (*a*) the secondary waves would occur *in the autumn*, and (*b*) they would be more severe in character than the "primary wave of last spring."

No such forecast as (*a*) was made, and it would have been a foolishly wild guess, inasmuch as the present secondary wave occurred more than twice as early as any previous "secondary wave" recorded in the history of the metropolis. (I know of no other place for which equally minute and accurate statistics are available.)

That this is so is further shown by the following statement taken from the monthly Medical Supplement compiled by the Medical Research Committee, dated Oct. 1st, 1918:—

"It is, unfortunately, only too certain that a second and more severe wave of influenza will spread over Europe in a few months."

No special foresight is needed to anticipate that influenza, if it recurs in winter, will be a more serious disease than in July; but when this last statement, which, it may be observed, is inconsistent with other published statements, was made the "secondary wave" already was well on its way to an unexampled maximum, having caused during September serious mortality in South Africa, the United States, India, and some parts of Europe.

If the forecast in the last quotation is to be verified it will mean a further epidemic of influenza which has not yet materialised.

DIFFICULTY OF PREVENTIVE MEASURES IN WAR TIME.

The point would not be worth pursuing, except for the implication that more could have been done to avert the present pandemic; and it is only to elucidate this point that I make a further observation. Warnings of possible "secondary waves" in the presence of much endemic influenza, or immediately after a superadded epidemic has declined, would be useful if a prophylactic were available (none except one in the early experimental stage has been suggested), or, if by issuing advice the progress of an epidemic could be stayed. Neither of these conditions can be fulfilled. We are at present unable to prevent the spread of influenza by communal means, and the experience of every family invaded by influenza demonstrates the difficulty, amounting almost to impossibility, of preventing the spread of infection in the domestic circle.

Notwithstanding this, I did in my official capacity prepare in July last a memorandum for public use, but on the balance of considerations its distribution was not considered expedient at that time. There are national circumstances in which the major duty is to "carry on," even when risk to health and life is involved. This duty has arisen as regards influenza among the belligerent forces, both our own and of the enemy, milder cases being treated in the lines; it has arisen among munition workers and other workers engaged in work of urgent national importance; it has arisen on a gigantic scale in connexion with the transport during 1918 of many hundreds of thousands of troops to this country and to France from overseas. In each of the cases cited some lives might have been saved, spread of infection diminished, great suffering avoided, if the known sick could have been isolated from the healthy; if rigid exclusion of known sick and drastic increase of floor-space for each person could have been enforced in factories, workplaces, barracks, and ships; if overcrowding could have been regardlessly prohibited. But it was necessary to "carry on," and the relentless needs of warfare justified incurring this risk of spreading infection and the associated creation of a more virulent type of disease or of mixed diseases.

The same problem has arisen in connexion with crowded trains, trams, and buses. These doubtless are prolific sources of infection, but the service cannot immediately be increased, and meanwhile the vast army of workers must not be impeded by regulations as to overcrowding of vehicles in their efforts to go to work and to return home, and I have had no hesitation in recommending the Local Government Board to advise police authorities to this effect.

THE PROBLEM OF PREVENTIVE MEASURES IN TIMES OF PEACE.

But we may consider the preventability of influenza from the standpoint of possibilities in time of peace, and ask whether we are prepared to pay the heavy price in personal restrictions which its prevention—if even then it be possible—will necessarily imply until further means of prevention, so far undiscovered, become available.

The problem of preventing influenza is part of the wider problem of the prevention of the entire group of catarrhal diseases, with the added problem as to whether the occult causes of pandemicity of influenza can be discovered and their action averted. Hitherto we have no clue to these, and our only hope of improvement lies in means to be devised for preventing catarrhal diseases, by diminishing infection, by reducing susceptibility, or both.

The measure of our present impotence is given by the inability of medical science to ensure us against acute nasopharyngeal catarrh or a "common cold." I do not overlook the occasional "hits" of autogenous inoculation. A "common cold" does not appear in our national death statistics; but probably it is a more frequent cause of diminished efficiency, if not also of death, than any of the acute infectious diseases, with the possible exception of measles and whooping-cough, not only by occasionally initiating ear abscesses, purulent infections of the bony cavities of the skull and face and meningitis, but especially because of its common ending in chronic bronchitis, and because it opens the way for meningococcal, pneumococcal, streptococcal, and tuberculous infections. And yet we have no entirely trustworthy means of preventing common colds. The nearest approach to a general truth in regard to these colds is that life continuously in the open air secures relative immunity from attack.

An initial practical difficulty in such prevention is that the patient for several days may not fully recognise his condition, and it seems likely that infection is chiefly spread during these earlier stages. It remains true, however, as stated in my recent official Memorandum, that—

"If every person who is suffering from ..... catarrh ..... took all possible precautions, the present disability and mortality from catarrhal epidemics would be materially reduced."

UNKNOWN CAUSES OF PANDEMICS.

I have referred above to the unknown causes which, for instance, in 1803, 1833, 1837, 1847, 1890, and again this year, have been responsible for world-wide spread of influenza, limited in its rapidity only by the speed of human travel, and multiplying so rapidly as to create the illusion of almost simultaneous origin in many countries.

One somewhat improbable hypothesis is that nearly simultaneous enhancement of the potency of endemic influenza virus occurs throughout the world. A fair working hypothesis is to regard influenza as a specific infectious disease which is always present sporadically in urban communities, widespread epidemics of it only occurring when a more exalted strain of the same virus is introduced from without.

The source of the more exalted virus can only be guessed. If we were to confine our outlook to the present pandemic it

[3] I notice that Captain Greenwood, in THE LANCET of Nov. 9th, quotes the solitary experience of a small agricultural district in Weardale in 1891 as a further example of a July epidemic followed by an October outbreak. The scattered character of this district is more consistent with the view that two independent outbreaks occurred; furthermore, we are not concerned with village outbreaks, but with the general trend of national events.

would be easy to blame the vast meeting of men of different nations under circumstances of overcrowding in large masses in this and other countries, some of whom had had no previous opportunity of acquiring even temporary immunity. But such an explanation fails to explain the earlier pandemics, which spread apart from exceptional world movements.

In the 1890 epidemic foreign origin and rapid spread of imported infection undoubtedly occurred in this country; it is highly probable that in the present year events have pursued the same course.

It has been surmised that the accidental contact of the hypothetical influenza virus with a native population which has not had the opportunity to acquire relative immunity from attack or death leads to an enhancement of the virulence of the contagion, and that it is thus enabled to commence its travels. This hypothesis does not appear to me to be satisfactory. The initial experience of the Fijians in regard to measles will be quoted in support; but those who re-read Dr. Corney's original account of that outbreak, as I have recently done, will note that the early cases in this first outbreak in the islands of Fiji were mild in character, and that among portions of the population who were under hygienic and medical control the fatality was low at other stages of the devastating outbreak. Experience of measles in armies is that it is sometimes as serious as on "virgin soil." It was so in the war of North *v.* South, and it has been extremely severe in the present war. It is possible that this has occurred especially in New Zealand and other troops from the remoter parts of Britain and of Greater Britain; but the same troops were simultaneously suffering from massive invasion by Pfeiffer's bacillus, by streptococci, and by pneumococci. The excessive fatality of measles in warfare is explicable by the combined invasion of several viruses, without need for recourse to the hypothesis of a specially unprotected population.

The measles problem is very similar to the influenza problem. In both, so far as our present knowledge goes, the chief hope of saving life lies in preventing, or in diminishing, the mortality from the streptococcal and pneumococcal pneumonia in these diseases, and research work in these directions is greatly needed.

It is evident that we are ignorant of the causes of pandemics of influenza at irregular intervals, and their occurrence has never, so far as I know, been anticipated.

We are still obliged to think of unknown factors; and I can repeat the admission of similar ignorance in regard to cerebro-spinal fever made by me elsewhere:[4]

> In epidemic times "strains make their appearance which possess greater intrinsic capacity for invading the tissues than the strains current in non epidemic seasons. As epidemics are intermittent, this emergence of more virulent strains must be due to intermittent causes; and it is still necessary to assume the action of some unknown influence, telluric, climatic, or other, which becomes operative under conditions of which we remain ignorant."

Influence of the War.

But although no satisfactory explanation is known of the causes exciting either the minor or the major epidemics of influenza, there can be no doubt that the movements of the recent war have been responsible on a large scale for its increased virulence. During the summer months of this year migration from country to country, from America, Canada, Australia, New Zealand, and South Africa to England and France, was occurring each month to an extent of several hundred thousand persons; and migrations in the opposite direction were also taking place on a large scale. The voyages of these troops occurred at a time of submarine dangers with a necessarily limited supply of ships; furthermore, influenza and streptococcal pneumonia were previously prevalent in oversea camps; and it would have been surprising had not this marvellously rapid and successful transportation of troops been carried through at a heavy cost in communicable disease. There is no reasonable doubt that through these months contagia possessing enhanced virulence were being brought into this country. The circumstances, in fact, bear a close resemblance to those under which cerebro-spinal fever first became considerably epidemic in this country in 1915

In attempting to trace the course of influenza in the present year it must be noted that the story cannot be told completely until Army and Navy statistics and civilian statistics for many countries become available, and any views now stated may need revision as the result of further national and international information.

Increasing Control of Disease.

It will be evident that we have a long road to travel before acute catarrhal affections can be brought within human control. The list of preventable and curable diseases has steadily lengthened. A first group of these comprises typhoid and typhus fevers and small-pox, which are entirely controllable and in large measure controlled. Dysentery, cholera, malaria, and plague also have their place in this group. A second group of partially controlled diseases comprises diphtheria and scarlet fever, although, like rheumatic fever, these diseases are subject to cyclical changes in distribution related to years of relative drought. Tuberculosis and syphilis are in the same group, and there is no adequate reason against their early transfer to the first group.

Measles, whooping-cough, acute poliomyelitis, and cerebro-spinal fever form a group in which infection appears to arise similarly to that of ordinary catarrhs and influenza, and their prevention so far similarly is only possible to a limited extent. For measles, whooping-cough, catarrhs, and influenza the chief present hope consists in attempts to diminish attack by or death from pulmonary complications.

Desiderata.

I may in conclusion indicate a few early desiderata in the investigation of influenza.

1. It would greatly facilitate further investigation if epidemic catarrhs, whether influenzal or other, were studied bacteriologically, especially in their early stages in selected populations—e.g., of institutions—and if a similar study were made of cases of bronchitis and of pneumonia in different localities and for a series of years. The work already begun by the Medical Research Committee will doubtless be of great value in this and other directions.

2. If such collective information is to have its maximum utility it will be necessary to ensure that observations by different bacteriologists are made by comparable methods.

3. The study of the epidemiology of influenza during the present war has been hampered by the necessary secrecy as to military and naval outbreaks, and by the failure of the ordinary international information coming into our official possession from consuls, foreign journals, &c. It will be possible partially to piece together the story of the present outbreak from the reports which medical officers of health have been requested to prepare; but information from the services will be needed to furnish a less incomplete story.

The civilian reports from different districts, so far as they have reached me, show a remarkable change in the age incidence of deaths from influenza during the present year; so much so as to have led to a not infrequently expressed opinion that we must be concerned with a different disease. Dr. Stevenson, in his contribution to the present discussion, will throw further light on this and other points.

Possibilities of Control.

The control of epidemic catarrhs may be considered from the point of view of the prevention of attack, or the prevention of complications. The possibilities of prevention of attack pending further medical discovery are limited; but under peace conditions the avoidance of aggregation of large units, especially for sleeping, are among the obvious indications. Whether persons affected with catarrh will in the future submit to wear veils or respirators is doubtful; but nurses of influenza patients should adopt this precaution. The utility of prophylactic vaccines remains to be demonstrated.

The prevention of pneumonia by vaccines is a more hopeful possibility; and it is possible that greater attention to the hygiene of the mouth and naso-pharynx both before and during attacks of influenza would have good effect. The gentle irrigation of nose and throat with a weak saline or antiseptic solution appears to have succeeded in diminishing pulmonary complications in measles, and might be equally beneficial in influenza.

The present pandemic will not have been suffered in vain if intensive investigation is pursued on catarrhal diseases in general, and if these great causes of national disability and mortality are brought more nearly under control.

4 Preface to Reports on Cerebro-Spinal Fever (Local Government Board, N.S., No. 114).

GENERAL PRINCIPLES IN THE TREATMENT OF INFLUENZA,

WITH SOME DETAILS APPROPRIATE TO TYPES OF CASES OCCURRING IN THE PRESENT EPIDEMIC.

BY SIR THOMAS HORDER, M.D. LOND.,
ASSISTANT PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL, ETC.

THE treatment of influenza by specific inoculation, by immune sera, and by specific drugs is very much a matter of *tot homines tot sententiae*. Time alone can adjudicate upon the claims made for a variety of remedies that are on trial during the present epidemic. I am not here concerned with any discussion or advocacy of these measures. More important for the time being, probably, than any one or any number of them is the promptness with which the general conduct of the case is established and the thoroughness with which it is carried out. Not only may these things be of vital importance to the individual patient, they are also of great importance to the uninfected public. *Every case of the disease treated upon sound general principles is a contribution to preventive medicine.* And every case in which these principles are neglected is a threat to public safety. In so far as the individual case is concerned, promptness and thoroughness do more than meet the actual indications of the moment; they give the patient confidence that he will "win through," and they often prevent by anticipation those dread complications, shorn of which the disease is not really alarming in its nature. The treatment of influenza, despite specific efforts at aborting the course of the disease, must be regarded as an "expectant" treatment. But in medicine expectancy should not connote inactivity nor an attitude of "wait and see." The line of treatment advocated in this short article claims no originality. It is merely an attempt to put in writing the actual plan of campaign resulting from an individual experience gained entirely at the bedside of a considerable number of patients, concerning whose treatment the writer has deliberated jointly with a number of colleagues. It is obviously open to much criticism, but it may be useful to some, not because their experience has been less, but because they may like to know the practice of someone else and compare it with their own. The dogmatic mode of setting down some of the points in the scheme of treatment is adopted merely for the sake of brevity and precision.

With the mild cases and, whether mild or not, with the cases running a brief and favourable course of two or three days, I shall not concern myself. Inasmuch as no one can possibly foretell which cases are going to follow this benign course, the treatment of the more severe type covers them. And it is well to enforce the warning that wisdom lies in considering any case at its period of invasion potentially a severe one, not to say potentially a desperate one. If this principle were followed, both by the patient before he seeks advice and by the doctor after he has first given it, the disease would lose much of its terrors. Handicapped as the practitioner is just now by great dearth of efficient nurses, and overloaded himself by work owing to the paucity of doctors left in charge of civilian practice, it must needs be that treatment is much less adequate than is desirable. It is all the more important to give precise directions to the friends, and to such nurses as may be available, including definite instructions as to what they should *not* do. I shall consider the principles of treatment and some details under four heads which are, I think, sufficiently clear not to require explanation.

(i.) *Severe Cases without Pulmonary or other Serious Complications.*

With the first symptoms of the disease order the patient to bed and keep him there until a week after his temperature has become normal, and only allow him to get up then if examination of the heart and lungs reveals no signs of disease. Choose the largest available room that is provided with good-sized windows and clear out of it all superfluous furniture. If the patient is found to have gone to bed in a very small room and a larger room near by can be used as the sick-room move him into the latter as soon as possible. Open the windows widely day and night, bad atmospheric conditions notwithstanding. Dispense with blinds and curtains. Disregard "light restrictions." Fortunately the authorities have now waived these. Despite this fact, however—so hard a thing is habit—it is quite common to find the benefits of an open window largely neutralised by a blind, and perhaps by a heavy curtain as well. Regard all screens with distrust, and arrange the bed near the centre of the room, far away from all cul-de-sacs. Aim at a room temperature of 60° F., obtained by an open fire if central heating is not employed. If the ideal of free ventilation with warmth cannot be secured, then warmth must be sacrificed rather than ventilation. *Not only does the neglect of proper aerotherapy seriously prejudice recovery in the event of pulmonary complications, it undoubtedly tends much to induce these. It is the most important point in the treatment of all cases.* Adjust the bed-clothes to the patient's temperature. Use sheets and blankets only; disallow down quilts and counterpanes; it is wise not to tempt the nurse or friends by leaving such things in the room.

Confine *the diet* to hot fluids, given frequently, and do not aim at "feeding up" the patient. Avoid meat extracts and strong broths. Thank the friends for their offers of turtle soup, advise acceptance of the gift, but keep it in reserve for the period of convalescence. Do not give alcohol during this early stage of the disease; in a simple febrile attack it is not required at all unless the patient is elderly. See that *the bowels* are well opened by a double dose of the patient's customary aperient; if he has none, give calomel gr. ½ every hour for four doses and follow this by a hot saline. Sponge the patient all over with warm water twice daily. Put no faith in *drugs* as specific measures, whether quinine, salicin, or what not. Give aspirin and Dover's powder, āā gr. x., as early as possible, and repeat in six or eight hours. Follow this by a simple diaphoretic mixture. If *headache* is severe in spite of this treatment, give phenacetin gr. v. with caffein gr. ii. four-hourly for four doses. If *the stomach* gives trouble and the tongue is foul, order sod. bicarb. and sod. sulphocarb., āā gr. x., with glycer. acid. carbol. ♏ x. and aq. menth. pip. ad ℥i. six-hourly, and be sure that the feeds are well diluted. For *vomiting*, when this is a feature of the case, reduce all feeds to a minimum, or abstain from them altogether for 48 hours, give minim doses of tr. iodi in one drachm of water hourly for six doses, and inject a pint of normal saline into the rectum twice or three times during the period of starvation.

The *distressing and ofttimes ceaseless cough* is generally the most difficult problem. A host of remedies is in use; the fact that they are legion is the best proof that none of them is very useful. Do not forget that local applications to the chest (*vide* (ii.)) are often of service in allaying cough. Remember also that when the origin of the cough is irritability of the upper air-passages inhalations of tr. benzoini co. (4 parts) with menthol or eucalyptus (1 part) are useful. Failing this a spray containing chloretone and menthol, āā 2 per cent., in liquid paraffin, may be used to the nose and throat. But these local measures are of little avail in the essential cough of the disease. I have found syr. coccillanæ co., syr. codeiæ, and linct. terp. heroin co. of some value. In the most intractable cases I prescribe syr. chloral ℥ss., ammon. brom. gr. x., ext. glycyrrhiz. liq. ♏xx., &c., four-hourly for four doses.

Sleeplessness calls first of all for a general review of the programme of treatment: ventilation of the room, control of pyrexia, posture in bed, the question of stimulants, &c. If none of these points seems capable of better adjustment, try a sedative draught containing ammon. brom. gr. xx. and tr. valerian. ammon. ♏ xx. If not successful, I use paraldehyde in drachm doses twice or three times during the night to secure a good sleep. The best cloak for its unpleasant taste is tr. quillaiæ and tr. aurantii āā ♏ xx. with water to one ounce. If vomiting is present, give the paraldehyde ℥ii. in normal saline solution ℥ii. as a rectal injection. As a last resort I use chloral hydrate gr. xx. (with ammon. brom.), believing it to be of less prejudice to the heart than any members of the veronal group and more efficacious than either trional or sulphonal. I avoid morphia for the treatment of sleeplessness or delirium; and the result of hyoscine, upon the only occasion I saw it used for the control of these troubles, was such as to put the drug wholly out of court as a therapeutic agent of service in this disease.

If, now, defervescence takes place, by crisis or by lysis, further treatment resolves itself into taking care to avoid relapse and into measures designed to restore nerve and heart

strength. These will not be discussed here. But there are two other possible types of case, over and above (i.), both of which tax the practitioner to the utmost. In some cases the two types are superimposed.

(ii.) *Intensely "Toxic" Cases, Tending to, or Actually Exhibiting, Hyperpyrexia.*

All the emphasis laid upon free ventilation must now be redoubled. Cradle the patient, as was formerly customary in typhoid fever with persistently high temperature. Failing this, insist upon very little bedclothes. *Remember*, and teach the nurse or friends, *that the thermometer, and not the patient's sensations, is the true guide to the amount of bedclothes and the presence or absence of hot-water bottles.* Sponge the whole body frequently with tepid water, and if the temperature is unaffected by this, use water at room temperature, or cooled below this point. Prevent the piling on of blankets after the sponging, because it is during the first hour or two *after* the sponging that the chief fall in the temperature occurs. Even good nurses often fail to understand this, and will complain that the sponging was ineffectual, the while one finds the patient's complaint of chilliness has led to the use of several blankets and some hot-water bottles. Should the temperature be obstinate yet—and in every case where it is 106° or higher—proceed direct to the cold pack, which must, if necessary, be prepared with ice-cold water, and repeated as often as is indicated by the thermometer. Do not fear "shock to the heart"; there is probably no shock to the heart so great as a continued state of hyperpyrexia. Even if pulmonary congestion is present, which, indeed, it usually is in all these severe cases, this treatment is not contra-indicated. Hot drinks are given frequently during these processes, and volatile stimulants including brandy or whisky. *Aspirin and all so-called febrifuge drugs must be rigidly excluded from the treatment during this phase of the disease.* Perseverance with these hydro-therapeutic measures, whose virtues have unfortunately been lost sight of to a great extent by the present generation of practitioners, will often be rewarded by great improvement in the facies, pulse, and nerve tone of the patient; it is certain that one of the gravest dangers in the disease may be largely averted by their means. Most of these cases require brandy or whisky to counteract circulatory failure, and nearly always they suffer from troublesome insomnia, which should be met as advised under (i.). Should the state of the heart give anxiety, the measures referred to under (iii.) in connexion with this organ must be resorted to. This type of influenza, occurring quite frequently during the present epidemic, responds in most encouraging fashion to prompt and careful handling.

(iii.) *The Pulmonary Type.*

The treatment of those complications of influenza which affect the respiratory organs—catarrh of the upper respiratory tract, bronchitis, lobar pneumonia, and pleurisy—follows in the main the usual practice when these diseases occur independently of influenza. By the "pulmonary type" of case I mean that class of patients in whom there develops quite early in the disease, even from the invasion stage in fulminating cases, intense acute congestion of the bases of the lungs, with cyanosis, persistent cough, the spitting of pinkish frothy mucus (it may be in large quantity), and cardiac embarrassment. So soon as the beginning of this trouble is detected it is well to use large local applications which combine moist heat with counter-irritation. If nursing help is available nothing is better than linseed meal and mustard poultices (linseed meal 8 parts, mustard 1 part), renewed every four to six hours until the skin is reddened. Choose the most congested part for the application, but ensure freedom of respiration by avoiding tight bandaging. Antiphlogistine is also good, as are equivalent preparations now obtainable at the chemists. The well-known Gamgee jacket thoroughly deserves its popularity, and, if properly made and fitted, it enables the patient to remain in a full current of air without fear of "chills." Requiring less skill than poultices, but not to be despised, are stimulating liniments, like camphor, chloroform, and turpentine, diluted with an equal quantity of oil, and used liberally. Do not wait for the arrival of signs of consolidation of the lung before embarking upon these local measures. In this type of case volatile stimulants, sedative expectorants, and diaphoretics are the most helpful drugs. Such are sp. ætheris co., the iodides in small amount, bromide and chloride of ammonium, tr. senegæ, tr. belladonnæ, and liq. ammon. acetatis. Avoid drugs that are apt to be depressing, such as antimony and ipecachuana. In most of these cases brandy or whisky is indicated in small and periodic doses. All feeds must be warm, despite the desire that patients sometimes show for cold drinks and for ice. The use of ammon. carb. is a vexed point; in any but small doses it sometimes tends to increase cough, and when there are little or no sputa the drug is of doubtful value. The treatment of cough has been considered already (*vide* (i.)). Oxygen should be given in all severe cases of this type of the disease, warmed by passage through hot water or alcohol.

The condition of the heart must be estimated more by the general state of the patient (facies, cyanosis, dyspnœa, delirium, posture) than by the pulse frequency. If unsatisfactory the volatile stimulants already employed must be supplemented by strychnine (gr. 1/30) and by camphor in oil (gr. iii. in 15 minims), injected alternately, the former subcutaneously, the latter intramuscularly, every six, four, or even two hours, according to the severity of the condition. If still further supplementary measures are needed the best appears to be strophanthin, gr. 1/500 in 15–20 minims of sterile normal saline solution, injected slowly into a vein of the ante-cubital fossa. This may be repeated in 8–12 hours.

In both of these severe types of the disease, (ii.) and (iii.), reliance must not be placed upon aperients to ensure good evacuation of the bowels. Enemata should be used daily, with as little disturbance of the patient as possible, and avoiding injections of large bulk. In this way the intestine, often in a state of paresis, is cleared of much toxic material and the patient's heart is relieved from the strain of an ordinary stool.

(iv.) *The Stage of Exhaustion.*

The fever having subsided and the acute symptoms passed, there is seen in many cases a state of extreme cardiac and nervous fatigue. This state requires great caution. If the patient attempts to overcome the condition by effort he risks either a relapse of his disease or an attack of heart failure, either of which may be very serious. Strict recumbency, perseverance with stimulants, and gradual increase in the quantity and quality of the food are the only measures needed to ensure complete recovery; at least, so far as the dangers of the disease are concerned. For even in the cases of extreme bradycardia that are occasionally seen (and the writer has met with a pulse of 30 persisting for five days in a boy of 17 years) the prognosis does not appear to be other than favourable.

THE INCIDENCE OF *BACILLUS INFLUENZÆ* (PFEIFFER) IN THE PRESENT INFLUENZA EPIDEMIC.

BY JAMES McINTOSH, M.D. ABERD.*

(*From the Bacteriological Laboratory of the London Hospital*, Professor W. BULLOCH, F.R.S.)

SINCE the discovery of the bacillus of influenza by Pfeiffer in 1892, towards the end of the 1889–92 panepidemic, there has been a considerable amount of discussion as to whether this bacillus is or is not the etiological agent of acute influenza. This controversy has continued during the present epidemic owing to the failure to demonstrate the organism in typical cases.

Cause of Conflicting Results.

An able and elaborate review of the investigations in this direction has appeared in the Medical Supplement to the *Daily Review of the Foreign Press* for October, 1918,[1] which clearly shows the widespread failure to demonstrate the bacillus of Pfeiffer with any degree of constancy. In fact, so numerous have been the failures that grave doubts are cast on the part played by the influenza bacillus as the causative agent of the present epidemic. Out of a large number of workers few found the bacillus with any degree of constancy. Matthews,[2] however, isolated the bacillus in every case (12) examined; Dietrich found it in his first seven post-mortem examinations; Bergmann isolated it in 15 out of 20 sputa examined. Since the above review was written, however, Eyre and Lowe[3]

* Working on behalf of the Medical Research Committee.

[1] Medical Supplement (compiled by the Medical Research Committee) to the Daily Review of the Foreign Press, Oct. 1st, 1918.

[2] THE LANCET, July 27th, 1918. [3] THE LANCET, Oct. 12th, 1918.

isolated it from 12 out of 14 sputa, while in Germany Neufeld and Papamarku,[4] Pfeiffer, Gotschlich, and Uhlenhuth report that in the more recent cases they have found the bacillus not infrequently. There are two possible factors concerned in the production of the negative results; either the bacillus of influenza is not present in the majority of cases or the methods and media used for its isolation are at fault. From the results given below we can at once dismiss the first contention; for the second there is more to be said, as the *B. influenzæ* belongs to the delicate group of hæmophilic bacteria which require special media for their isolation. Up to the present it has generally been supposed that ordinary laboratory media to which some blood had been added were sufficient. In fact, Davis stated that as small a quantity as 1 in 180,000 of hæmoglobin was all that was necessary.

Characteristics of B. influenzæ.

The bacillus of influenza is one of the smallest microbes visible, measuring 1 to 2μ in length; it possesses a considerable degree of "pleomorphism." At times it appears as a short thin rod with rounded ends, while at others it is so short that its appearance is that of a small coccus. The bacillus is Gram-negative and does not stain well with the majority of bacterial stains, best results being obtained with carbol-fuchsin. The bacillus will not grow on ordinary medium until blood or hæmoglobin has been added, and if the medium has been made slightly alkaline good growths can be obtained. In sputum large numbers of the microorganism may be present and at times almost uncontaminated with other bacteria. Often the bacilli are arranged in small groups, which are very characteristic. But a microscopic diagnosis of *B. influenzæ* is far from satisfactory, and in my experience only possible on a few occasions. At times the bacillus may present a bipolar appearance owing to the centre part not having taken up the stain properly. The colony on suitable medium may vary from a fraction of a millimetre to 2 or 3 millimetres in diameter. It is circular, flat, and translucent, in subcultures the growth is often confluent, and on trypsinised blood medium possesses a brown appearance. On pigeon blood agar the growth is much whiter. Then, unless the strain is subcultured at least every second day, there is a great tendency for it to die out.

I have thought it necessary to mention the above characteristics of the *B. influenzæ* in order that it may be seen what I have considered as its criteria. Forms which do not come up to the above standards have been rigorously excluded, and on this account it is quite possible that some of the larger forms rejected are really the so-called pseudo-influenzal forms of the *B. influenzæ*.

Present Investigation.

In the early summer of 1918 when the disease first assumed epidemic form in London material from a small number of cases and from post-mortem examinations was examined with unsuccessful results as regards the presence of *B. influenzæ*. In these investigations ordinary blood-agar (human blood) was employed. From this it was concluded, perhaps rather rashly, that *B. influenzæ* did not play an important part in the causation of the epidemic, and the matter was not pursued further. No single type of bacterium was found with any degree of constancy; in some it was streptococci, in others Gram-negative bacilli similar to the *B. bipolaris equisepticus*, and in a few a pleomorphic micrococcus morphologically and culturally identical with the coccus which Rosenow has described as constantly present in poliomyelitis. With the recrudescence of the epidemic this autumn, and bearing in mind the results achieved by Matthews with trypsinised blood, it was resolved again to investigate the condition. The successful results obtained with this medium are detailed below.

Media Employed.

For the isolation of the bacillus I have used exclusively trypsinised blood-agar made according to the formula supplied by Captain S. R. Douglas. The directions are as follows: In a series of test-tubes, containing 8 c.cm. of sterile normal saline solution to which has been added 0·25 per cent. of anhydrous sod. carbonate, is placed 0·5 c.cm. of sterile trypsin (Allen and Hanburys). The tubes are incubated to test sterility, and, if sterile, 2 c.cm. of blood are added to each. The tubes are then placed in the incubator and shaken from time to time until the blood is completely digested and of a brown colour. This will take at least 48 hours. The trypsinised blood-agar is then prepared by adding 1–2 c.cm. of the digested blood to 5 c.cm. of 3 per cent. agar.

For the purpose of growing the *B. influenzæ* in subcultures this medium is excellent, but for the purpose of isolation the blood must be digested for a longer period, as it is only after 10–14 days incubation that the medium will be found to have developed its full inhibitory properties as regards the growth of other bacteria. This inhibition of other bacteria, as pointed out by Matthews, is, in my opinion, one of the most useful features of the medium. In fact, without this property the isolation of the *B. influenzæ* from post-mortem material on ordinary blood-containing media is almost impossible owing to its overgrowth by the other bacteria present. The selective power of this medium must be regarded as comparable to that of Löffler serum for the bacillus of diphtheria or milk for the bacillus of Welch.

Trypsinised blood medium has the disadvantage, however, that the influenza bacillus tends to die out on it very easily. For the purpose of keeping the strains going I have found pigeon's blood-agar most suitable. Pigeon's blood is added to sterile distilled water in the proportion of 1 to 10 and then 1 c.cm. of a sterile $\frac{1}{4}$ per cent. solution of anhydrous sodium carbonate added. The agar is prepared by adding 1 c.cm. of this laked blood to 5 c.cm. of melted agar.

Technique of Isolation.

For the isolation of the *B. influenzæ* from sputum, pus, or other pathological exudate a small platinum loopful of the material should be spread over a couple of trypsinised blood-agar slopes. In the case of throat swabs, the swab should be rubbed gently over a plate or a couple of tubes. The tubes or plates are then examined after having been incubated overnight, and the likely colonies picked off and subcultures and film preparations made. On this medium the young isolated colonies have a characteristic appearance and so can be picked off with considerable facility. For the purpose of identification the appearance of the bacillus, its size, the lack of affinity for stains, and the inability to grow on non-hæmoglobin-containing media were considered sufficient.

Types of Material Examined.

In this paper I have considered it unnecessary to give full descriptions of the individual cases examined, as it is proposed to do so later when a full acount of the investigations is made. A résumé of the main features of the types dealt with is given below.

(1) *Broncho-pneumonic cases.*—(*a*) Post-mortem material: In the first instance, examinations were confined to material obtained from post-mortem examinations. Samples for bacteriological investigation were taken from bronchial pus and from the affected lung tissue. In the majority of instances the lungs showed extensive changes. They were greatly congested and showed numerous broncho-pneumonic areas. The bronchial mucous membrane also showed considerable changes, while the smaller bronchi usually contained a certain amount of pus. The most striking feature is undoubtedly the great congestion of the lung tissue, and the areas of actual hæmorrhage. In fact, the whole appearance might be in most instances regarded as a hæmorrhagic broncho-pneumonia.

(2) *Acute broncho-pneumonia.*—In these cases the sputum was examined when obtainable and also any pathological exudate such as pleuritic fluids. The sputum from the different cases showed considerable variation, in some being thin and watery, although in the majority it was thick, mucoid, and tenacious, only in a few was it muco-purulent. In a large number it was distinctly rusty in colour. From a certain number of these cases blood cultures were made. The material was collected only from those cases which had a temperature varying between 100° and 103° F.

(3) *Acute uncomplicated cases.*—In this article the results given are limited to those cases where the posterior naso-pharynx was examined. Swabs were taken and incubated on hæmoglobin-containing media. The great majority of these cases were in the acute stage of the disease, before any definite pulmonary complications had developed. There was fever varying from 101°–104° F., great prostration, flushed face, suffusion of the eyes, but in no case was there coryza, although some had an irritating cough.

Results of Bacteriological Examinations.

(1) *Broncho-pneumonic Cases.*—(a) *Post-mortem material.*

Case No.	1	2	3	6	9	12	13	14	15	16	20	23	25	26	30	31	33	34	60
Result...	+	+	+	+	0	0	+	+	+	0	+	0	+	+	+	0	+	0	+

Total = 19 cases examined, positive 13 (68·3 per cent.).

\+ = Positive as regards the demonstration of *B. influenzæ*.
0 = Negative as regards the demonstration of *B. influenzæ*.

[4] Deut. med. Woch., Oct. 24th, 1918.

(b) *Sputum.*

Case No.	4	5	7	17	18	19	21	22	24	27	29	32	47
Result...	+	+	+	+	0	+	+	+	+	+	+	+	0

Case No.	48	49	50	51	52	53	55	56	57	58	59	62
Result...	+	0	+	+	+	+	+	+	+	0	+	+

Total of 25 cases examined, of which 21 cases were positive, making a percentage of 84·0.

(c) *Blood Cultures.*—Blood cultures were done on some ten of the above cases, and all proved negative as regards the presence of *B. influenzæ*. In two cases done shortly before death bacterial growths were obtained—in the one a streptococcus and in the other a Gram-negative coccus.

(2) *Acute Influenza.*—In this instance the posterior naso-pharynx only was examined.

Case No.	...	35	36	37	38	39	40	41	42	43	44	45	46
Result	...	+	0	0	+	+	+	+	+	0	+	+	0

Total 12 cases, of which 8 gave positive results (66·8 per cent.)

Altogether 56 unselected cases have been examined to date, and from these the bacillus of influenza was cultured on 42 occasions (75·0 per cent.).

Discussion of Results.

As regards the mere association of the bacillus of influenza with the cases examined the results speak for themselves. The percentage of positive results over the whole series was 74·5, although in the different groups the figures vary somewhat. In the case of the sputum from broncho-pneumonic cases the percentage was 84·5; in the post-mortem material obtained from a similar series of cases it was 68·3, while in the naso-pharynx of the acute uncomplicated cases the figure was 66·8. With more prolonged investigations I am sure the number of positive findings of the bacillus of influenza could be increased, as under the conditions of the present time one could only spare the minimum amount of time and labour necessary. In addition, there is the probability that a number of the clinical diagnoses may have been at fault as well as the pathological, which would tend to lower the percentage. The later error, however, can be adjusted when histological examination of the post-mortem material has been completed.

Relative Frequency of Other Bacteria.

In this article it will be sufficient to indicate the relative frequency of the other bacteria found in the cases. On the whole, film examinations have given the impression that Gram-negative bacteria have a tendency to predominate in a good number of the cases, and cultural examinations have confirmed this. Gram-negative diplococci were present on numerous occasions; while cultures showed that some of these belonged to the meningococcus type, more frequently these cocci were of the *Pharyngis siccus* type. In others large Gram-negative bacilli belonging to the coliform group were present, some of which proved to be the *Bacillus proteus* and others the *Bacillus pneumoniæ* (Friedländer). In addition, especially in the naso-pharynx of acute cases, a small Gram-negative bacillus rather larger than the influenza bacillus was isolated. This bacillus was identical with one isolated during the summer epidemic, and was distinctly bipolar in type, with rounded ends. At times the stained bacillus presented an appearance not at all unlike that of the *Bacillus pestis*.

Of the Gram-positive bacteria, the most frequent were staphylococci, both aureus and albus, then streptococci, and lastly pneumococci. In this series a marked feature has been the absence of pneumococci in the various sputa examined, and in not more than two cases were they present in such numbers as to lead one to infer that they played an important part in the process. Of four pleuritic fluids examined two gave growths of a fine streptococcus, one a pure culture of pneumococcus, and one a pure growth of *B. influenzæ*. The slimy condition which the lungs develop in many cases after a short exposure to the air is apparently due to the *B. proteus*.

The Rôle of the Bacillus in Etiology.

Unlike the influenza bacillus, these various other bacteria do not predominate with anything like the same degree of constancy. These results, however, do not in themselves prove that the *B. influenzæ* is the cause of influenza, but only that this bacillus is present in the majority of the cases. One must bear in mind that the mere association of a micro-organism with a particular disease does not entitle one to describe it as the cause. For the purpose of illustration it is sufficient to mention the *Bacillus suipestifer* and hog-cholera, or *Bacillus proteus* (Strain X.) and typhus fever. The constant presence of the bacillus of influenza is suggestive that it plays an etiological rôle in the production of the condition known as influenza. Conclusive evidence can only be produced as the result of further experimental work.

In acute influenza there is probably an invasion of the respiratory tract by the influenza bacillus, their growth is accompanied by the production of toxic bodies, which injure the mucosa and on absorption produce a general malaise. In the more severe cases the fine bronchi and the alveoli of the lungs are affected. In the latter the walls of the capillaries, as well as the walls of the alveoli, are injured, with the result that a serous exudate takes place. In parts this exudate completely fills up the alveoli, and on this account sections of the affected lung produce a picture strikingly like that produced by phosgene poisoning. The second stage of the disease consists of an infection of the damaged tissues and serous exudate, with one or several of the pathogenic bacteria which are to be found normally in the respiratory tract. Thus a secondary septic broncho-pneumonia is set up.

In conclusion, one must admit that the almost constant presence of the bacillus of influenza is suggestive of an etiological rôle, and that prophylactic inoculations against this organism might be successfully employed to combat the disease.

Further, I wish to express my indebtedness to Professor Bulloch for his interest and advice on many points.

PROVISIONAL NOTES

ON THE PATHOLOGY OF THE PRESENT EPIDEMIC.

BY P. FILDES, M.B., B.C.,

HONORARY SURGEON-LIEUTENANT COMMANDER, R.N.V.R.

(*Working in the Navy on Behalf of the Medical Research Committee*);

S. L. BAKER, M.R.C.S., L.R.C.P.,

TEMPORARY SURGEON-LIEUTENANT, R.N.;

AND

W. R. THOMPSON, M.SC. CORNELL.

(*From the Laboratory, R.N. Hospital, Haslar.*)

THE arrival and progress of the influenza pandemic in London appears to have been unexpected among the population and to have caused a certain extent of dismay. The curious isolation of different communities due to the difficulty of travel and the absence of press facilities has put back the distribution of common knowledge to what it was a hundred years ago. It is possible to read about occurrences in South Africa or Bombay, but news from towns in this country only filters through gradually and often in a distorted form. Thus, while the influenza epidemic has been proceeding sporadically or acutely in Portsmouth for months, the fact has hardly been referred to outside.

Here in Portsmouth the disease has been more or less endemic since the outbreak of "Spanish influenza" in the spring. Pneumonia since that time has been prevalent in the Navy, but since that time it has been certainly more prevalent than usual, and has been the subject of considerable inquiry and study. The number of cases of empyema was remarkable. In these were found not only pneumococci, but also in many cases hæmolytic streptococci, which gave all the ordinary reactions of *Streptococcus pyogenes*.

The general opinion at that time was that the cases were due primarily to either of these organisms or, indeed, to other "respiratory" organisms, since *Streptococcus viridans* and *Streptococcus mucosus* were sometimes met with. It was the general impression that "respiratory" bacteria had taken on an increased virulence, owing to the somewhat unsatisfactory weather and the presence of large numbers of young "new entries" in the barracks. The cases were very largely confined to these young "new entries."

The question of influenza as a factor in the disease was discussed and studied, but owing to the complete absence of bacteriological support the causative importance of this bacillus was discredited.

At the end of August, however, an acute alteration took place in the aspect of the disease. The cases among "new entries" became more and more numerous and the clinical aspect more and more acute. It became obvious that a serious epidemic had broken out. Large numbers of cases of acute pneumonia were admitted to hospital, and among these the death-rate was very high. Localising signs such as empyema became less frequent; indeed, death occurred before these could develop. The outstanding feature of the disease was an acute septicæmia of a particularly fulminating type.

At that time the epidemic was very largely confined to the young naval "new entries," and this fact, together with the unusual symptoms, led to all manner of curious suggestions as to its origin. It was even suggested that the disease might be pneumonic plague, while, of course, the foolish seized upon "vaccination" or "inoculation" as the cause, without considering whether either of these protective measures had been already carried out or not.

As the epidemic progressed the age-incidence became widened and all types of men became affected, and finally, as was inevitable, the civil population came under its influence. Clinically, it became more obvious that the acuter symptoms were nearly always preceded by "catarrh," and the question of influenza as the initial infection again came into prominence. Bacteriologically, however, we were unable to obtain any evidence of this; neither in the sputum nor in throat swabs could we find influenza bacilli. Large numbers of cultures and microscopic examinations, post mortem, were equally unsuccessful. In the trachea, lungs, and blood we now found almost exclusively the same hæmolytic *Streptococcus pyogenes*.

We were therefore inclined to the view that this must be a primary streptococcal pneumonia, although it was obvious that the objections to such a view were serious. On the other hand, we were conscious of the fact that the demonstration of influenza bacilli is at all times difficult, and particularly so under the septic conditions which were before us, and therefore when Dr. John Matthews [1] published his technical method for growing *B. influenzæ* we at once went into the question further.

Among the first cases examined with a digested blood medium comparable to Matthews's, we obtained cultures of *B. influenzæ* mixed with large numbers of streptococci from the tonsil after death. In subsequent investigations, using a medium founded upon that of Levinthal (which we refer to as "K" medium) we have found influenza bacilli in so many men suffering from influenza without pneumonia, and in the organs of men dying from pneumonia, that we are of opinion that it is unnecessary to look further than this organism for the cause of the epidemic, the streptococci and the other organisms which have been mentioned being only secondary infections upon lungs already affected by *B. influenzæ*.

The difference in the bacterial flora obtained by the use of these media is so remarkable that we are prepared to admit that our earlier conclusions were incorrect, and that *B. influenzæ* was probably the real cause in most of the cases of pneumonia which have been occurring during the last six months. Under these circumstances it may be an assistance to those who still implicate various streptococci or who are discussing the possibility of an "invisible virus" to have our tentative results so far as they can be carried when half our staff is sick.

Ante-mortem Findings.

We have examined the naso-pharynx in 15 cases of influenza in whom there were no obvious signs of pneumonia, and in 12 have isolated *B. influenzæ*. Several of these patients later developed a fatal pneumonia, but, unfortunately, no autopsy was permitted. In each case we have made only *one* culture, and the number of positive results would, undoubtedly, have been much higher if we had made several examinations or if we had been working the whole time with a satisfactory medium. Sometimes the growth has been profuse, but more often a few colonies only develop among the numerous Gram-negative cocci, pneumococci, and streptococci.

We have also examined the naso-pharynx of 71 men who were apparently healthy and obtained 15 positive cultures This finding has an epidemiological interest.

Single samples of *sputum* have been examined from 106 cases and *B. influenzæ* has been found in 45.

[1] THE LANCET, 1918, ii, 104.

Influenza bacilli can often be cultured from sputa in which it is difficult or impossible to recognise them microscopically. In a small number, however, bacilli were so numerous and pure that they could hardly be missed even by Gram's stain, and we are satisfied that we did not overlook cases of this type in the earlier months of the epidemic. In the great majority of the sputa, including those in which copious growths are obtained, the microscopic picture is inconclusive so far as *B. influenzæ* is concerned, but pneumococci and streptococci abound as usual. It is true that with a very intense stain, such as that which we call "multicolour blue," a few minute bacilli may be found, often in clumps, but we very seldom get a picture which convinces us that influenza bacilli are present, and the subsequent copious growths are often surprising.

We have made *blood cultures* from a number of men with pure influenza with negative results, and similar negative results have been obtained with the *urine*.

Post-mortem Findings.

(*a*) *Macroscopic pathology.*—The post-mortem appearances of a rapidly fatal case will best indicate the type of disease with which we have been dealing here.

Externally: The body of a well-developed muscular young man, aged 18; marked cyanosis of lips and finger-nails; a quantity of blood exuding from mouth. *Thorax:* 200 c.cm. of deeply blood-stained watery fluid in left pleural cavity. A trace of similar fluid in right chest. The parietal pleura on both sides is injected and shows scattered purpuric patches. The *pericardium* contains a little clear blood-tinged fluid. The *heart* shows nothing remarkable beyond hæmolytic staining of the endocardium; the heart-muscle is firm and appears in good condition. *Left lung:* The lower lobe is a dark purple colour and shows a fine fibrinous roughening in places; it retains its shape on removal and is heavy; it feels soft and jelly-like, with several firmer areas 2 or 3 cm. in diameter scattered about in the lung substance. The upper lobe is similarly affected in its posterior part, but in the anterior portion it is spongy and feels aerated. On section the lower lobe is dark-red colour and airless, being full of a thin hæmorrhagic exudate which flows out from the cut surface. In the places corresponding to the firmer portions described above there are found solid, dark-red, rather dry areas. Some of these extend to the surface of the lung and resemble infarcts in appearance; others, however, are more or less spherical masses situated centrally in the lung. The lower part of the upper lobe is similarly infiltrated by a thin hæmorrhagic exudate, but the upper part is aerated and shows a congested spongy lung substance. The *right lung* is less affected than the left, the upper lobe being aerated and showing a red spongy surface. The bronchial tree throughout the lungs is intensely injected and contains bloody fluid which pours out into the trachea. The naso-pharynx, pharynx, larynx, and trachea are much injected. This injection is most marked in the trachea, especially in the lower part, which is a dark purple colour. The tonsils are prominent and injected and contain a few beads of pus. The cervical and paratracheal glands are injected, the latter being a dark purple; the gland below the tracheal bifurcation is enlarged and very soft and hæmorrhagic, as are the glands at the hila of the lungs. *Abdomen:* Peritoneum and intestines appear normal. Spleen not enlarged. On section, slightly swollen red pulp. *Kidneys:* Cortex rather opaque in appearance, slightly swollen, no hæmorrhages or other abnormalities detected. *Suprarenals* show dark plum-coloured medullæ, the left being the most affected. *Bladder, &c.:* Nothing remarkable. *Brain:* Some injection of smaller vessels upon the cerebral cortex. No signs of meningitis. No hæmorrhage.

The above is a rapidly fatal case showing no reaction to the infection. The patient appears to have been drowned by the exudate into the lungs rather than killed by the septicæmia.

In cases of longer standing there has been, in addition to the hæmorrhagic condition, a marked broncho-pneumonia with pus in the smaller tubes, and sometimes areas of grey hepatisation, as seen in lobar pneumonia. In several cases there has been a purulent bronchitis and peri-bronchitis, the lung presenting a marbled appearance owing to the purulent infiltration of the bronchial walls; the purulent infiltration can also be seen on the surface of the lung as a white peri-lobular network. Empyema is very common, there being, as a rule, a thin yellowish opalescent fluid with a sediment of thicker pus in the most dependent part. Pyopericardium is frequent. The spleen shows evidence of reaction, being enlarged and having a swollen, often diffluent, creamy or dark-red pulp. The kidneys often show severe parenchymatous degeneration, but in only one case

has there been an obvious nephritis. In a few cases dying ten days or so after the onset of the disease the heart muscle appeared considerably affected, being very flabby and having the appearance of parenchymatous degeneration.

(*b*) *Bacteriology*.—The organism which is immediately responsible for the above pathological picture is a hæmolytic streptococcus; it does not ferment inulin, and grows in long chains as a sediment in broth. It is found in enormous numbers in the lungs and in the pleural and pericardial pus when this is present. From the blood it can be obtained post mortem, usually in pure culture. The coccus, though forming long chains in fluid exudates, often shows diplococcal forms in the tissues, so that it cannot always be recognised as a streptococcus in films. At the beginning of the epidemic this streptococcus was the only organism of importance which could be recovered from the tissues or blood of the cases examined; when, however, the new media became available for the investigation of the cases it was possible to prove, what had already been suspected, that the influenza bacillus was the real cause of the disease.

Previous to the adoption of these media much time was spent examining films from the lung exudates, scrapings from the trachea, &c., without obtaining any evidence of the presence of the influenza bacillus In the first case in which the bacillus was demonstrated it was found in pus from the enlarged tonsils, and in this it could be seen, with appropriate staining as described elsewhere, in large numbers, chiefly intracellular. Although in this case films from all parts of the respiratory tract were examined, the bacilli could not be detected anywhere else and streptococci in enormous numbers dominated the picture. At the present time we are obtaining cultures of *B. influenzæ* from every post-mortem examination upon these pneumonia cases. In the lungs the bacilli are obtained with certainty only from the most healthy parts; the obviously diseased portions are so full of cocci that the bacillus has apparently been exterminated and its detection has generally been impossible. It is obtained fairly constantly from the trachea and bronchi; in the case of the bronchi those in the healthier parts of the lungs yield the best results. Pus from the deeper parts of the tonsils gives on culture scattered colonies of *B. influenzæ* amongst innumerable streptococci. In one case a culture from blood taken from the jugular vein yielded a few colonies of *B. influenzæ* and a copious growth of streptococci.

When now these bacteriological findings, ante- and post-mortem, are reviewed as a whole, taking into consideration the essentially superficial nature of many of the examinations and the difficulties met with in the preparation of a very delicate medium, it appears justifiable to us to suggest that *B. influenzæ* is very frequently present in the respiratory passages before death, and is present in the lungs and sometimes the blood after death so frequently as to suggest that the disease is constantly associated with and due to a *B. influenzæ* infection.

The Cultivation of B. influenzæ.

The classical blood-agar medium for the growth of influenza bacilli has been practically useless to us under the conditions met with.

We have already mentioned that we first used a digested blood medium akin to Matthews's, but we gave it up in favour of Levinthal's, which is simpler to prepare. We have had no opportunity to study the original description of this medium, but have worked entirely upon the reference to it in the Medical Supplement to the *Daily Review of the Foreign Press* (Oct. 1st, 1918) compiled by the Medical Research Committee. The principle of this medium is the addition of fresh blood to a flask of melted agar in a proportion of 1 in 20. The medium is brought to the boil and the coagulum aseptically filtered off "through gauze or paper."

There are factors in the preparation of this medium which are still obscure. We have several times made up batches which are entirely useless; indeed, we have made up two batches from the same materials and at the same time, and one has been excellent and the other useless. We are almost satisfied that the factor in these cases is the filtration through "gauze or paper." Neither of these substances should ever be used, but *glass-wool only*, presumably because the paper absorbs the essential "vitamins" (Jordan Lloyd).

We have not yet decided whether the blood must be *fresh*. We use citrated ox or sheep blood and find this to be satisfactory if collected once a week. Whether a "stock" citrated blood, laked with distilled water and sterilised with chloroform, according to the technique of one of us, is suitable we are not yet certain.

The technique of preparation of "K" medium is simple.

A flask of ordinary 2 per cent. meat agar is melted and reduced to 55° C. The agar need not have been "egged" or cleared in any way. One part in 20 of whole blood is then added and the flask placed in a water bath at about 60° C. The flask is constantly shaken while the water rises to the boil, and when this occurs it is left at rest for 10 minutes at the boiling point. In the meantime a flask carrying an ordinary filter funnel lightly packed half full with glass wool has been autoclaved. The boiled agar-blood mixture is poured through this wool without shaking and, if necessary, left in the steamer. Usually the filtration takes only a minute or two and the medium is then poured aseptically into a number of sterile tubes and sloped. No contaminations need arise during these manipulations.

The effect of this medium upon the growth of *B. influenzæ* is very remarkable. This bacillus is familiar to us as producing characteristic pin-point colonies on blood agar. The colonies grow no larger and seldom coalesce. On ordinary agar, the bacillus does not grow at all, but merely by adding the soluble products of a small quantity of boiled blood the growth on agar becomes as profuse and as confluent as the growth of typhoid. The size of the colony depends entirely upon the spacing. The common size is 2 mm., but when colonies are well isolated they often attain no less than 5 mm. The growth recalls that of meningococci on serum agar, but is more transparent. Against a dark background the colonies are also somewhat bluer. They are very easy to distinguish from streptococci or pneumococci. The growth is very readily emulsified to form a stable suspension.

The Identification of B. influenzæ.

The microscopic appearance of *B. influenzæ* upon "K" medium is very characteristic. It is very small and thin. The bacillus is usually so short that it resembles a coccus. The longer bacillary forms which are familiar upon blood agar do not develop on "K" medium. Films made from the larger colonies a few days old show a curious degeneration of the bacteria. They have largely broken up into an amorphous débris in which individual bacteria are hardly recognisable, but subcultures from such colonies yield normally profuse growths. The viability of these bacteria appears to be quite prolonged. Even on slope cultures on "K" they live for several days, sometimes for as much as a week, and in capped "stab" cultures in "K" all our strains survive 15 days at least.

The affinity of *B. influenzæ* for stains is feeble, and this constitutes one of the chief difficulties in its demonstration. It is, of course, negative to Gram, but the affinity for the counter stain is so feeble that this method is useless for its detection in pathological material. The stain which we have found most satisfactory is a methylene blue preparation akin to polychrome-methylene blue, which we call "multicolour blue." We made this stain by dissolving 10 g. of methylene blue in a litre of 1 per cent. sodium bicarbonate solution and steaming for two hours. A few drops of this stain are placed upon the slide and this is then heated until steam arises. In the case of a pure culture the stain is then rinsed off and the slide dried, but when dealing with a pathological exudate the slide, after rinsing, should be momentarily placed in alcohol which contains one drop of glacial acetic acid per 100 c.cm. It is then rinsed and examined.

There are at present no specific tests which can be applied to identify *B. influenzæ*. We rely upon the morphological appearance and the growth on blood agar, with an absence of growth on ordinary agar. Most strains grow with the typical discrete, pin-point colonies on blood agar, but some develop rather larger confluent colonies up to 1 mm. The bacillus is, of course, non-motile. Fermentation reactions are now being studied and attempts are being made to prepare agglutinating serum. Rabbits will tolerate very large doses, even two slope cultures of living bacilli.

Prophylaxis of Influenza.

It appears to us that the only practical measure which is likely to be effective to control the present epidemic is a prophylactic vaccine treatment. In instituting such a measure it is necessary to decide whether it is more profitable to attempt to prevent the onset of influenza or to

prevent the complications which are the cause of death. On all grounds we consider that the former is the more satisfactory aim, since if the influenza can be prevented the complications will not arise. Therefore, we consider that *B. influenzæ* should be the main basis of the vaccine. We have already prepared large quantities of this vaccine and have experimented with it on volunteers.

The question of the dose to be employed must be governed by several factors. It must not be so large that a danger of a pronounced negative phase will arise, because this would be dangerous when the epidemic is already present and sources of infection are universal. Neither must it be too small to be effective. Further, it is undesirable to produce marked local reactions, since these would create too much dislocation in the carrying on of employment. We are not in favour of giving two doses only, because if these are large enough to be effective a negative phase may follow. We therefore subdivide the first dose into two and give three.

The spacing of doses which we have adopted for the moment is fairly short. The first dose is given on the first day and the others on the fourth and eighth. The quantities given are 50 million, 166 million, and 500 million. The second dose gives rise to some local reaction, and it is possible that the third will have to be reduced.

It has been decided that these vaccines shall be used only upon volunteers, and, since the allegations which have already appeared in certain sections of the press will probably militate against men coming forward, we wish the immediate effects of the vaccine to be as mild as possible; otherwise we are afraid that this process, which may well be followed by excellent results, will be discredited and never receive an adequate trial.

THREE CASES OF MALIGNANT DISEASE OF THE UPPER EXTREMITY.

BY J. W. GEARY GRANT, F.R.C.S. ENG.,
ACTING ASSISTANT SURGEON, KING EDWARD VII. HOSPITAL, CARDIFF.

THE following cases of malignant disease in the region of the shoulder present, I think, some points of interest.

Case of Berger's Operation.

The first case, one in which several limited operations had been performed for an epithelioma of the hand, where ultimately the disease had extensively involved the axillary glands and lymphatic vessels, demonstrates the advantages which Berger's operation gives in sweeping away, without a difficult, tedious, and possibly incomplete dissection of the axilla, all possibly infected tissues.

CASE 1.—Patient aged 43. In 1894 suffered from abscesses about both ankles, presumably tubercular. Various operations were performed at different hospitals, and in 1898 a sore formed on the back of the left thumb, which he attributes to a scratch becoming infected whilst dressing his foot. In 1902 the left foot was amputated at Bristol by Mr. R. G. P. Lansdown, and he has had no further trouble with the lower extremities. The sore on the thumb refused to heal, and in October, 1907, X ray treatment was begun and continued at the various places where he resided for over a year. In all, some 50 exposures were given. In February, 1909, he consulted me, and as far as I remember now, there was an indolent ulcer with smooth red surface on the terminal phalanx of the left thumb on its dorsal aspect, the surrounding skin showing numerous minute telangiectases. The sore healed under applications of scarlet red ointment. In October, 1913, it again broke down, and in May, 1914, as it showed no signs of healing, I amputated at the interphalangeal joint by a palmar flap. He had no further trouble until October, 1916, when a blister formed at the end of the stump. Early in 1917 it showed the obvious appearance of the epitheliomatous ulcer, and was amputated through the carpo-metacarpal joint. Recurrence promptly followed in the scar, and a hard cord was found running up the lower part of the palmar aspect of the forearm on the radial side, which on examination was found to be a lymphatic vessel filled with carcinoma cells. The original ulcer on examination was a squamous-celled carcinoma. I then amputated the forearm just below the elbow, removing all the fat and the epitrochlear gland. Glands from the axilla and the cephalic gland, removed for examination, showed no signs of malignancy. In May, however, glands were felt in the axilla. He was admitted to the King Edward VII. Hospital and operated on with the intention of clearing the axilla, but as soon as an incision was made it was obvious that this was impossible. There was an extensive glandular involvement and a large thrombosed lymphatic vessel the size of a large crow-quill was found running by and adherent to the axillary vein. His consent to amputation had not been obtained, and the wound was closed. I felt that a Berger's operation held out the best chance of a radical operation and I decided to perform a fore-quarter amputation.

Three days later, under open ether, and after a preliminary injection of morphia, I made an incision over the clavicle and resected the middle third with a Gigli's saw. The pectoralis major was separated and the subclavius divided and the neuro-vascular bundle exposed. The artery was ligated at the junction of the axillary with the subclavian (this was lower than it should have been). The arm was elevated to empty it of blood, and the vein secured at the same level. The three cords of the brachial plexus were

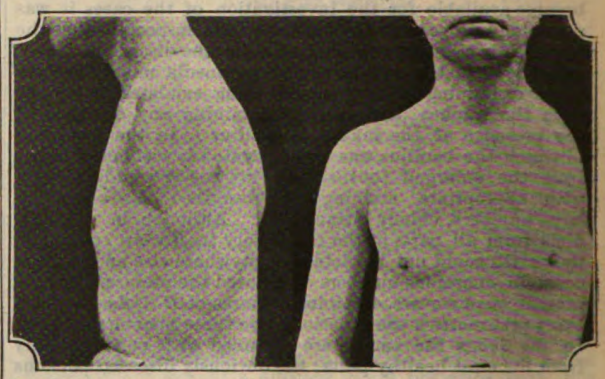


FIG. 1.—Shows smooth rounded outline of shoulder with almost linear scar, well on front of chest owing to absence of pectoro-axillary flap.

injected with a 4 per cent. solution of novocaine, and after a few minutes divided. The original incision was carried out along the acromion and spine, and then down to the posterior axillary fold. This was joined by another passing from the mid-point of the clavicle in a curve with the concavity outwards so as to leave practically no anterior flap, the object being to get as far away as possible from the infected axillary contents. Similarly, the pectorals were divided well inwards and reflected with the fascia over the serratus magnus, which was divided a little further out. The cervico-dorsal flap was then reflected, the trapezius, levator anguli, and muscles attached to the posterior border of the scapula divided, the transversalis cervicis and supra-scapular arteries secured, and the limb removed. In spite of the absence of the pectoro-axillary flap there was ample skin covering. There was very considerable shock, which was treated by continuous rectal saline and the usual methods, and the next day his condition was very good. The wound healed by first intention.

A month later, glands having been found in the neck, an incision was made from the mastoid to the clavicle and outwards to the trapezius, which was partially reflected, and the whole of the fat and glands removed *en bloc*. These showed evidence of infiltration with carcinoma. At the end of August a small lump was found near the anterior border of the trapezius and was removed. From June to the present date he received 25 exposures to X rays. So far no further signs of the disease have manifested themselves, and he has been for the past six months carrying on his ordinary duties. Fig. 1 shows his appearance.

Case of Amputation at the Shoulder.

About the same time I had the following case in hospital.

CASE 2.—Patient had a very extensive carcinomatous ulcer arising in the scar of a large burn involving the greater part of the skin of the right upper arm. I amputated at the shoulder, having to make irregular flaps extending on to the chest, as the scar trenched on the axilla and chest wall. The skin covering was not adequate, and part of the wound healed by granulation. The difficulty of feeling sure the axilla was completely cleared in this case afforded a marked contrast with the last, where everything was swept away *en bloc*, without a tedious dissection. Here one had to think about getting flaps to cover the stump of the scapula and acromion. The shock was certainly not so great, but I feel that Berger's operation would have been the better procedure.

The man received seven exposures to X rays in as many months, the limited number being due to the distance at which he lived. He reports that he is in perfect health at present.

Berger's Operation.

In Berger's operation fat, glands, and muscles with their fascial lymphatic network are swept away in one piece, and this entails the minimum risk of cutting through infected tissues, and therefore fulfils the principal canon in the surgery of malignant disease. The cosmetic result (which, as a matter of fact, should not enter into consideration) is, I think, at least as good as in amputation at the shoulder-joint, and retention of the shoulder-girdle is of no functional importance. In either case if an artificial limb is worn it is for appearance only.

The operation itself, a somewhat formidable one, has, according to Keen, a mortality of 6 per cent. The indications given by Jacobson and Rowlands and in other works are (1) certain cases of malignant disease too extensive for amputation at the shoulder; (2) certain cases of injury; (3) gangrene and infections. In the latter two I should imagine the operation mortality would be very much higher. I have not seen records of its use in military surgery, but conceivably it might be indicated in spreading gangrene as a very heroic measure.

As regards the steps of the operation, these are fully described in the text-books, but certain points are worthy of note.

1. A free removal of the clavicle facilitates finding the subclavian artery and vein, and also assists in securing the transverse cervical and suprascapular arteries with their veins, which may give considerable trouble. Le Conte disarticulates at the sterno-clavicular joint for this reason, but one would imagine this procedure, laying bare the great vessels at their emergence from the thorax, a more dangerous procedure.

Sir F. T. Chavasse divides both pectorals near the chest, turns them outwards, and uses the loop of the anterior thoracic nerve as the guide to the axillary artery. By this means and by dividing the serratus magnus close to its origin from the ribs, and later the latissimus dorsi, the axilla can be removed with its contents intact.

2. Methods to diminish shock. Blocking by Crile's method each cord of the brachial plexus with a 0 5 per cent. solution of cocaine as soon as they are exposed and before ligation of the vessels is of great value. It might also be worth while to block the descending branches of the cervical plexus by injecting them at their point of emergence at the middle of the posterior border of the sterno-mastoid. This would render the whole skin incision anæsthetic.

3. Farabeuf's pectoro-axillary flap seems unduly full, and baggy flaps favour sepsis. With no anterior flap in this case there was abundant covering.

Case of Removal of Scapula.

The third case is one of a round-celled sarcoma of the scapula.

CASE 3.—Patient, aged 29, in September, 1916, commenced to have pain in his left shoulder, which he thought was rheumatism. Later a swelling the size of a golf ball appeared, which gradually increased in size. Dr. R. Cameron, under whose care he was, found the Wassermann test negative, and sent him to the hospital with the diagnosis of sarcoma. An aspirating needle only drew a little blood.

On March 30th, 1917, under open ether, I made an incision in the axilla with a view to ligature of the subscapular artery as the first step in removal of the scapula, when numerous small glands of a dusky purple colour were encountered. These were removed as high up as practicable without division of the pectorals and the subscapular vessels were ligated.

A T-shaped incision, one limb passing along the acromion and spine, the other along the vertebral border of the scapula, was made, and the corresponding flaps reflected. In exploring the growth with a view of seeing whether a partial removal was practicable, in separating the infraspinatus from the spine, the finger passed through an opening in the venter into the subscapular fossa. The trapezius and deltoid were separated from the attachments to the spine and the base of the acromion sawn through with a Gigli's saw. The muscles attached to the vertebral border, the scapular muscles, and the long tendon of the biceps with the capsule were divided, and the base of the coracoid cut through with bone-pliers, thus preserving the origins of the short head of the biceps and the coracobrachialis. The scapula was then removed after dividing the teres major and subscapularis. The trapezius and deltoid were sutured together.

There was considerable shock, and he was placed on continuous saline and the usual measures. Stitches were removed on the ninth day and primary union was obtained. An attempt was made to keep the limb in abduction on a Jones's abduction splint, but he could not be induced to keep this on, unfortunately, or he would have retained much more power of abduction.

On May 18th he was readmitted, a large mass having formed in the axilla, and two days later the axilla was cleared with division of the pectorals, which were subsequently sutured.

On June 13th, glands having appeared above the clavicle, a further operation was performed. The posterior triangle was exposed by an incision from the mastoid to the clavicle along the posterior border of the sterno-mastoid and outwards along the clavicle, and the whole of the fat from this space, from the mastoid to the clavicle and from under the trapezius, which was partially reflected, to the carotid sheath, was removed.

From April 30th he had received daily injections of Coley's fluid, starting with ¼ minim and increasing by ½ minim until with 3½ minims he had a fairly severe reaction. It was intermitted for a few days and then resumed. In all I think about 15 injections were given, but I have not the record by me. Prophylactic X ray exposures were given by Captain Owen Ll. Rhys at weekly or bi-weekly intervals, and up to the present date he has received 25 exposures. His present condition is shown in Fig. 2, and so far he appears in perfect health and shows no signs of recurrence. He has a very useful arm, except that voluntary abduction is limited to about 45°, and there is some limitation of both antero-posterior and rotatory movements. In view of the known malignancy of round-celled sarcoma of bone and the extensive invasion of glands that occurred, I cannot but think that the combination of Coley's fluid and X ray exposures had something to do with freedom from recurrence up to the present (November, 1918).

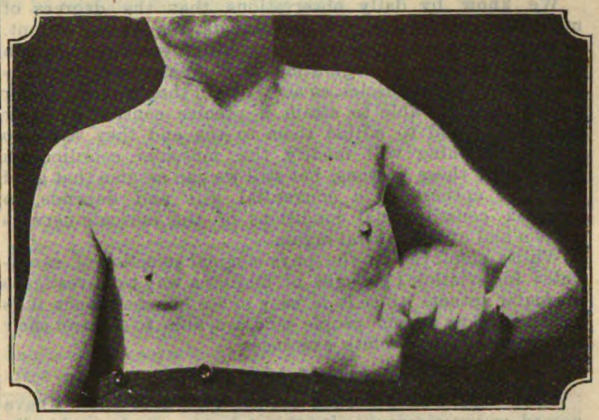

FIG. 2.—Showing full amount of voluntary abduction at false joint between head of humerus and chest wall. Range of active movement 45°.

I have had several other cases where I adopted this combination of post-operative treatment, but the time that has elapsed has not been sufficient to warrant any conclusion being drawn, although so far the results have been hopeful.

As regards the steps of this operation, which entails considerable shock, the following points may be noted :—

To use all ordinary measures for preventing shock, and possibly blocking the descending branches of the cervical plexus, might be worth trying, although this would only affect the skin incision. Preliminary ligature of the subscapular vessels should be done, and if there is any reason to suspect glandular involvement the pectoral muscles should be divided and the whole axilla cleared, as in a breast operation, with subsequent suturing of the muscles. Sarcoma of bone is prone to affect the glands, and if it is possible this should be done in all such cases.

Ligature of the suprascapular and posterior scapular vessels as soon as they can be exposed by reflecting the trapezius will save hæmorrnage in the later steps of the operation.

It can seldom be safe to leave the glenoid process, and it is doubtful if any better functional result will be secured by so doing, as all the surrounding muscles are divided and adhesions would form. It is, however, most important at an early stage to adopt some means to keep the arm in abduction to a right angle.

Cardiff.

THE ERGOESTESIOGRAPH:

AN APPARATUS FOR THE GRAPHICAL REPRESENTATION OF THE MUSCULAR APTITUDE OF CANDIDATES FOR AVIATION.

BY G. GALEOTTI,

PROFESSOR OF PATHOLOGY AT THE ROYAL UNIVERSITY OF NAPLES, IN CHARGE OF THE PSYCHO-PHYSIOLOGICAL LABORATORY FOR AVIATION.

IT is well known how much uncertainty still exists in regard to the senses (muscular, articular, tendinous sense, and more generally deep sensation) that allow us to appreciate the amount and strength of our movements so as to regulate them according to the intended aim. This uncertainty includes the fundamental scientific points of view as well as the method of investigations.

We know by daily observations that the degrees of muscular coördination of individuals are very different. Some people can execute with great adroitness and perfection all their movements, regulating in a precise way the contractions of their muscles, so as to attain their object. Other people are not able to attain a precise control of their movements and to adjust them to the end they strive to attain. Training will modify the muscular coördination capacity of these persons, but still we can assume that good muscular aptness is a congenital gift and depends on complex constitutional conditions of the musculo-nervous system and of the central organs.

Whilst employed in the physiological selection of candidates for aviation I thought of finding a way to investigate muscular aptness, since it is easy to see how necessary it is to select pilots among people who are able to control their movements with absolute exactness.

Description of the Apparatus.

To this end I have worked out the apparatus which I have named *ergoestesiograph*. Its object is to record graphically the individual manipulative ability in counterbalancing variable resistances.

The instrument is shown in Fig. 1. On a strong low table is pivoted a lever with unequal arms. On the long arm, A (60 cm. length), there slides a sleeve, B, which carries a hook, to which is attached a weight and a rod, C. The rod

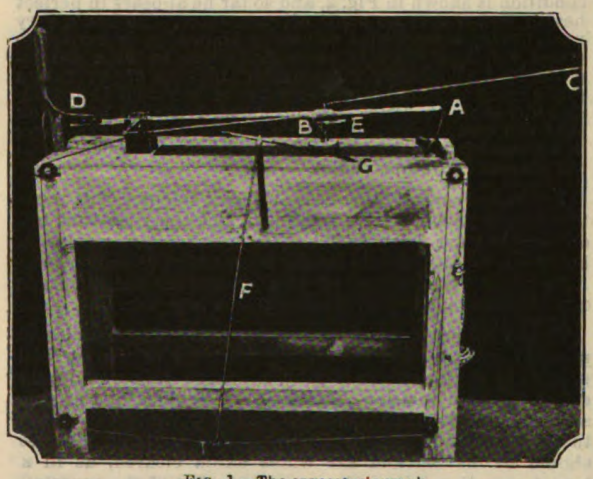

FIG. 1.—The ergoestesiograph.

serves to slide the sleeve and weight along the arm. On the short arm of the lever another small rectangular lever works, to which a handle is attached. A glance at the figure will show how, by pushing the handle forward, the arm A of the principal lever will rise. To this lever is attached a writing style, E, which traces on the revolving cylinder the oscillations of the lever. Another style, G, is attached at right angles to the rod F; this oscillates, and by means of a wire-and-pulley transmission traces on the same cylinder, according to the movements of the sleeve B, the displacements of the weight, and therefore the variations of the resistance.

The candidate and the observer are situated as shown in Fig. 2. The observer, by means of the rod C, slowly slides the sleeve B. The candidate, blindfolded, holds the handle, and *feeling* the variation in resistance, due to the sliding of the weight, tries to oppose it, and so to regulate his own muscular force as to keep the lever A always horizontal.

On the cylinder the writing styles trace two curves: one with large regular oscillations, which represent the variation of the resistance, and this I name *resistance curve;* the other represents the vibrations, uncertainties, and jumps of the muscles which attempt to compensate the variations of resistance; this curve may be called the *muscular curve.*

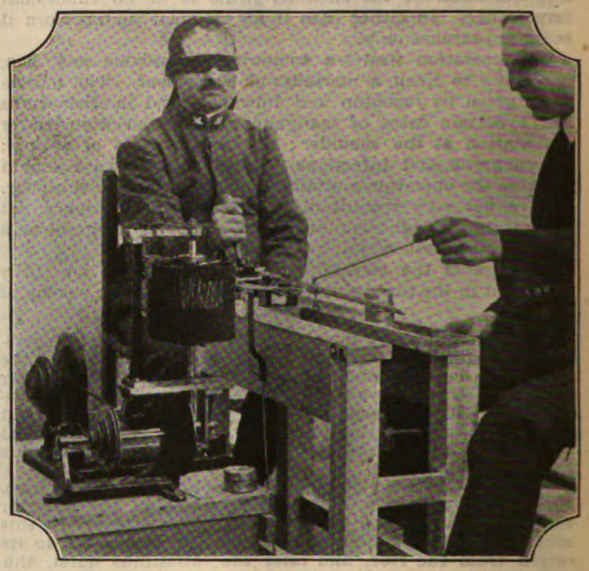

FIG. 2.—An experiment with the ergoestesiograph.

The experiment is usually conducted in two ways.

(1) The candidate places himself as shown in Fig. 2, and the slight movements he makes with his forearm are in the same plane of the lever A. I have named this *first position.*

(2) The candidate places himself laterally to the table; the plane in which the lever A moves is perpendicular to the forearm. I have named this *second position.* In this way the aptitude for forward and back movements, as well as for side movements, can be recorded.

In the first position the experiment is easier for the candidate, and the muscular curves are always more regular than those obtained in the second position.

Other data regarding these experiments are the following: The weight is 2 kg. for the first position and 1 kg. for the second. The variation of the resistance goes from 12 kg. (lowest apex in the curve of the resistance) to 2 kg. (highest apex in the same curve) in the first position; from 6 kg. to 1 kg. in the second. The displacing of the weight is so done that each oscillation has a period of about 10 seconds.

Results of Observations with the Instrument.

With this instrument I have already obtained a great number of tracings, and it may be said that these tracings have a personal type, like the ergograms obtained with Mosso's instrument.

I have experimented with various people—with individuals not accustomed to any kind of muscular work, with persons accustomed to various sports which require skill and exactness of movements, e.g., with horsemen, motor cyclists, automobile drivers, and aviators. Naturally, I specially concentrated my attention on the latter, and I have been able to experiment on a certain number of pilots. I have ascertained with satisfaction to myself that the best curves have been given by aviators who have shown the best records in flying, while curves not so good were obtained from untrained pilots and candidates still under instruction. I have also obtained quite good tracings from good riders, probably because they are trained to keep the reins in a state of correct tension by an adequate contraction of the muscles of the arm and forearm.

Thus, in this respect the instrument has shown itself to correspond to the aim for which it has been constructed—viz., to place on record evidence of the good or bad muscular coördinations of the individuals subjected to the experiment.

Theoretically, from an individual with perfect neuro-muscular mechanisms—that is, from a man capable of com-

pensating at every instant the variation of the resistance by an adequate contraction or relaxation of his muscles—a horizontal line should be obtained. But in practice that does not take place, and each subject will follow somewhat the oscillations of the resistance, so that even a very good muscular curve shows an undulating aspect.

Types of Curves Obtained.

The collected material, although not quite sufficient for allowing definite conclusions to be drawn, permits me, however, to give some hints on various types of curves obtained with my instrument. In these curves it may be noticed :—

(*a*) In the best cases the muscular curve maintains itself in a middle zone of the tracing ; that means that the person subjected to the experiment can appreciate and maintain the horizontal position of the lever. In other cases some people make curves which regularly and continually descend ; these persons do not feel that the tension of their muscles is gradually giving way ; other people instead make curves which continually rise—that is, they react to the variation of the resistance with an increasing muscular effort. Generally, the descending or ascending type remains with the same person, even if the experiment is repeated many times.

(*b*) The best curves are those in which the principal oscillations are uniform and not very high. Moderately good curves are those in which the principal oscillations, though uniform, are rather high ; this means that the candidate follows the variations of the resistance too easily—that is, he is not able to compensate them in a quick and exact way. Bad curves are those in which the oscillations are not uniform and vary very much in height.

(*c*) The presence of notches and jumps is the most important point to be considered. In very good curves the notches are very small and there are no jumps of the lever. This means that the candidate can augment and diminish in a uniform and steady way the contractions of his muscles. When he cannot do this there are vibrations and sudden strengthening and collapsing of the contractions —that is, the individual does not regulate his muscles evenly, and we have then those very irregular tracings which are characteristic of awkward persons.

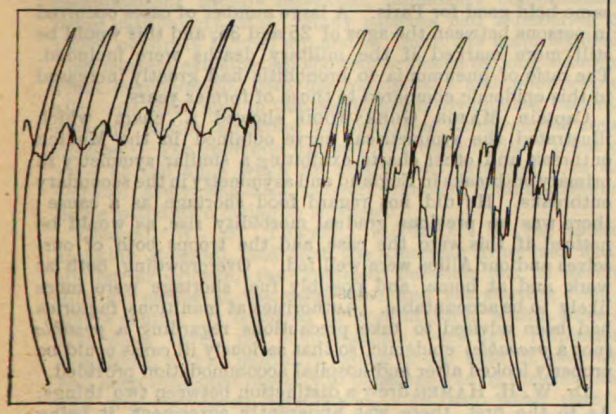

FIG. 3.—A good curve obtained from a famous aviator.

FIG. 4.—A bad curve obtained from an individual with poor muscular coördination.

These conclusions may be summarised as follows :—

(*a*) Good curves which show excellent muscular coördination : the curve remains in a middle horizontal zone ; principal oscillations are uniform and low, with few small notches and no jumps.

(*b*) Moderately good curves : ascending or descending curves ; curves with principal oscillations rather high and not uniform ; curves with many and pronounced notches.

(*c*) Bad curves, which show poor aptitude to regulate the muscular activities : uneven, irregular curves, with large notches and jumps.

As an example, in Fig. 3 a very good curve is reproduced, obtained from one of our best pilots, and in Fig. 4 a very bad curve, made by a person who possesses neither precision, skill, nor agility of movement, and therefore would never be able to become a safe aviator.

NEURASTHENIC AND HYSTERICAL CASES IN GENERAL MILITARY HOSPITALS.

BY R. H. TROTTER, M.D. MANCH.,
MAJOR, R.A.M.C. (T.C.); OFFICER IN CHARGE, MEDICAL WARDS, HUDDERSFIELD WAR HOSPITAL.

BY Army Council Instruction 712 of 1918, paragraph 4—

"Cases which it may not have been possible to send to one of the special hospitals mentioned in para. 2, and all other cases occurring in other central and auxiliary hospitals, will be transferred to one of those special hospitals as soon as the necessary accommodation is available."

Hysterical and neurasthenic patients, therefore, should only be found in the wards of a general hospital when they are awaiting transfer to a special hospital, or when they are suffering from some physicopathic condition which so far overshadows the psychopathic element in the case as to cause this element to be readily overlooked, or, if it is recognised, to be relegated to a secondary place.

Importance of Early Diagnosis and Treatment.

The object of the present contribution is to enforce the importance of being constantly on the look-out for such symptoms in patients admitted for physical disease, and, in cases admitted as neurasthenia, of adopting such treatment as is possible in a general hospital pending transfer, instead of leaving the patient untreated.

A vicious neuropathic habit speedily becomes fixed, and few cases coming within the scope of medical treatment partake more of the nature of those pathological emergencies which are usually supposed to be the exclusive property of the surgeon. It is, indeed, but a mild exaggeration to assert that early treatment in the psychoneuroses of war is as important as prompt surgical interference with the course of acute appendicitis. Yet there is a tendency, as soon as the diagnosis of neurasthenia or hysteria is made or confirmed after reception of a case so diagnosed overseas, to mark the patient for transfer to a neurological centre, and then to take little further interest in him, even though the interval before transfer takes place is occasionally extended to several weeks. There is also, perhaps as a part of the recent disposition throughout the profession to exalt surgery at the expense of medicine, an inclination in the surgical wards of all hospitals, both civil and military, to lose sight of the patient in striving after the extension of the field of surgery and the attainment of perfection in technique.

Though for continued treatment and complete cure of most of the motor, sensory, and visceral psychoneuroses, and of nearly all the psychical neuroses, the mental atmosphere and the facilities for subsequent open-air employment found in the neurological centres may be essential, the essentials for emergency treatment should be at hand in every general hospital. These essentials are accurate diagnosis, confident prognosis, understanding sympathy, and inexhaustible patience. Given these, many cases developing hysterical conditions whilst under treatment may be cured at once (a common example being hysterical aphonia and photophobia after gas poisoning), and other patients definitely hysterical may be transferred to the neurological centre when the vacancy is notified already on the high road to recovery.

Method of Treatment.

In the treatment of motor psychoneuroses I have followed lines similar to those suggested by Major A. F. Hurst.

The patient is subjected to partial isolation in a special case ward, but any irksome restriction is avoided. The nature of his ailment is explained to him in accordance with his capacity for understanding such an explanation, an exhaustive examination having preceded the diagnosis of a pithiatic condition. He is confidently assured of an early and complete recovery. If the motor psychosis takes a spastic form passive movements are performed until relaxation of the muscles is secured. If the "palsy" is flaccid the manipulation is carried on until a flicker of muscular contraction is elicited. During the manipulation the patient is assured with monotonous reiteration that recovery is about to take place and that it is a matter of absolute certainty, and any objections and difficulties are met and answered. At the least sign of muscular contraction he is urged to resist the passive movements, and often hours elapse before the muscular resistance becomes powerful enough to retain the "palsied" limb in a momentary rigidity. The manipulation is then suddenly interrupted, and the man, taken by surprise, maintains the limb for a second or two in the posture in which it has been suddenly abandoned

by the manipulator. From this point further progress is rapid, as the least intelligent subject can now be readily convinced of the unreality of his supposed paralysis. The principal danger if he has to wait some time before being passed to a neurological centre is the development of one of the fantastic habit gaits so easily acquired by recovering pithiatic paraplegics, but this is readily avoided by a little supervision. Exercise and such employment as is available should be resorted to at once, for to leave the patient with an idle brain is to court a relapse or a psychical neurosis.

Psychical neuroses are frequently amenable to a psycho-analytical talk, resolving doubts and difficulties and leading the sufferer back to a normal outlook upon life. Mild degrees of this condition are very common in the medical diseases of war. The patient confined to bed with an ailment which does not eliminate his neuropathic potential by overwhelming it with pain has time to think over his war experiences, and in this instance Cowley's lines—

> "Things which offend when present and affright
> In memory, well painted, move delight"—

are very far from the truth.

In the surgical injuries of war, on the other hand, the pithiatic symptoms are frequently determined by the surgical lesion, and tend to develop along the lines of motor and sensory psychoneuroses. It is an interesting speculation how far the reflex contractures of Babinski and Froment would be prevented by early neuropathic treatment. Certainly unceasing vigilance is called for in the surgical wards of a general military hospital to prevent development of neuropathic conditions.

Visceral neuroses are often aggravated by essays in abdominal surgery, though sometimes a temporary improvement may follow the operation.

Illustrative Cases.

The following cases recently coming under observation are illustrative of some of the foregoing remarks :—

1. S. E., aged 34. *Pleurisy and acute rheumatism with endocarditis.* In bed four months for this condition. Walked badly on getting up, and when at an auxiliary hospital fell on uneven ground and became paraplegic. When I undertook treatment of the paraplegia he had been in bed a further four months. After two and a half hours of manipulation combined with vigorous persuasion he got out of bed unassisted, and with some education recovery of walking power ensued. The V.D.H. necessitated his discharge from the Service.

2. E. H. R., aged 45. Transferred from France after attack of *acute gout in foot.* Diagnosis, "myalgia." Mother was paraplegic two and a half years, and man was confident that his condition resembled hers. Had been in bed five weeks when treatment undertaken, and recovery of walking power was effected after three-quarters of an hour.

3. V. W., aged 31. Sent home from India with *debility and chronic intestinal obstruction following dysentery.* Had trench fever in France before going to the East and had "terrible pains in the legs" ever since. The shin pain was a typical algia and disappeared almost at once under vigorous persuasion. He had been in bed nine months and believed that he would never walk again, but recovered the use of his legs after the usual treatment, and was walking about unaided 14 days after admission.

4. C. H., aged 23. *Paralysis* (unable to flicker a toe) *of both lower limbs and left arm.* Ankles supported by stirrups from thighs and air-cushion in use to prevent bed-sore. Passed as permanently unfit by a board in the East and disability estimated at 100 per cent. Been in bed eight months. As there was no immediate vacancy at a neurological centre I undertook treatment at once, and after some hours' treatment, as described, he was able to stand and walk, and within 14 days of admission was going out alone on pass.

5. T. S., aged 22. Sent home from the East diagnosed "*effects of heat,*" with history of severe sunstroke, but opinion expressed that part of the condition was functional. Total flaccid paraplegia and paralysis of left upper limb; athetosis-like movements of left side of eight months' duration; absolutely bedridden for six months. There being no immediate vacancy in a neurological centre treatment was undertaken five days after admission. In half an hour the athetosis had disappeared, in an hour the left upper limb was moving normally, and in three hours the patient walked into the hospital grounds with me.

6. B. H., aged 21. *Fractured pelvis* seven months ago. Never walked since, save with crutches, and then with difficulty. Performed all movements of limb and walked with stick after half an hour's treatment.

7. J. L., aged 35. *P.U.O.* Complained of depression and had marked tremor when under observation. Elicited that after being bombed when carrying comrades to a place of safety this incident had remained as a painful impression, repressed during waking, but recurring nightly in dreams. Urged to familiarise himself with every detail of the incident in his waking hours and to discuss with other men. In a fortnight all psychasthenic symptoms had disappeared. This case is typical of many.

8. W. L. M., aged 19. *Mutism.* Eight days before admission from overseas a shell burst close by when he was lying down waiting to attack. He remembers nothing further until he found himself in a trench with three wounded men of his company who had carried him thither. Has never spoken since. No external injury. Communicates by signs and writing. Treatment undertaken day after admission. Explanation, manipulation, and persuasion. Speech restored in half-an-hour.

The list could be extended, but I have said enough to show that by simple methods early cases developing in hospital can be cured at once, and established cases awaiting transfer need not necessarily be allowed to drift.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

Presentation of the Diploma of Honorary Fellowship to Sir Alfred Keogh, G.C.B.

A GENERAL meeting of the Fellows of the Royal Society of Medicine was held on Nov. 14th, Sir HUMPHRY ROLLESTON, K.C.B., the President, being in the chair, when the President presented the diploma of Honorary Fellowship to Sir Alfred Keogh, G.C.B., late Director-General of the Army Medical Service.

In presenting the diploma the PRESIDENT gave a brief sketch of Sir Alfred Keogh's career, pointing out his connexion with the R.A.M. College, his organisation of the Territorial R.A.M.C., and his truly Herculean task of creating an efficient medical service on a war basis, showing his wisdom by the free utilisation of available civil talent in the form of consultants and experts, successfully blending them with the Regular Service. Sir Alfred Keogh was the fifty-seventh British Honorary Fellow, there being but 146 Honorary Fellows since the establishment of the Medical and Chirurgical Society in 1805.

Discussion on Influenza.

Sir ARTHUR NEWSHOLME, K.C.B., opened the discussion on Influenza. His paper will be found in full on p. 689 of our present issue.

Epidemiology.

Dr. T. H. C. STEVENSON exhibited charts showing the difference in the age distribution in this and the earlier epidemics, in the July and September 1918 outbreak a very small proportion of cases occurring amongst old people. The same held good for Paris. A large number of cases occurred in persons between the ages of 25 and 35, and this would be still more marked if the military deaths were included. The ratio of pneumonia to bronchitis had greatly increased in this epidemic compared to those of former years.

Captain MAJOR GREENWOOD showed a chart which illustrated the symmetrical curve obtained in the Munich outbreak and other charts exhibiting a similar symmetry in primary outbreaks in England and asymmetry in the secondary outbreaks. He did not regard food shortage as a cause; there was no previous gradual morbidity rise, as would be noticed if this were the case, and the troops both of ourselves and our Allies were well fed. Overcrowding, both at work and at home, and possibly fuel shortage were more likely to be accountable. Authorities at munitions factories had been advised to take precautions regarding a *possible* (not a *probable*) epidemic, so that seriously ill cases could be properly looked after and hospital accommodation provided.

Dr. W. H. HAMER drew a distinction between two things. As to the first, there was apparently agreement, it being now admitted that there was a close relationship between outbreaks of cerebro-spinal fever, poliomyelitis, and polio-encephalitis, and outbreaks of influenza, bronchitis, and pneumonia. As to the second, there was not, perhaps, the same general consensus of opinion. It was claimed not only that these diseases prevailed in the same communities, either concurrently or in closely related sequence to one another, but also that two or more of them might, in certain phases of epidemicity, simultaneously affect members of the same household or other associated groups of persons. Work which had been done on the subject (of which he gave a brief review) pointed to a common cause operating in the epidemic diseases in question, but whilst some held that this cause was the same living organism, others maintained that the nexus which bound cerebro-spinal fever, poliomyelitis, polio-encephalitis, and encephalitis lethargica together with influenza, bronchitis, pneumonia, and epidemic catarrh was merely predisposing (telluric, climatic, &c.) and not an actual causal influence exerted by one and the same infecting agency operating in all of them. Sir Arthur Newsholme had added measles and whooping-cough to the group, but distinction should be made between these two diseases and those just enumerated; detailed evidence as to a very remarkable association of outbreaks in respect of their time distribution and of the presence of the several disease types in households and in groups of associated persons had been adduced in

the case of the former, but no similar intimate interrelationship between them and measles and whooping-cough had been demonstrated. He called attention to the fact that an important argument in favour of a *common infecting agency* in the first-named influenzal group of diseases was forthcoming in applying the principle known as the law of parsimony. The hypothesis that there was *one common infecting agency* fitted the facts and greatly simplified the necessary assumption. He pleaded for the application of William of Occam's razor—*Entia non sunt multiplicanda praeter necessitatem*—to the present case. The use of this instrument would not only reduce by some millions in London alone the number of carriers of the causal agent, many or all of whom were regarded by whole-hearted supporters of the healthy carrier doctrine as persons who should be segregated, but it would also enable a consistent workable theory of the case to case spread of influenza to be formulated. It would, by focussing attention upon one single cause instead of upon a congeries of secondary invaders, give research workers and statisticians a chance of studying the laws of influenzal epidemicity, and at the same time relieve preventive medicine of the need of carrying on its shoulders an impracticable working hypothesis.

Colonel SOLTAU said that influenza had been present in the Armies in France all during the war on a small scale. True bacteriological influenza was always present in the winter. The epidemic broke out in the first week in April in the Army in Northern France and spread to other areas. The spread was most marked amongst men who were sleeping or messing together. It was a mild form, there were no fatalities, and no cases had to be evacuated. It continued during May and broke out afresh in June, and continued during June, July, and August. This epidemic was very severe numerically, virulence increased steadily from the middle of June, and the proportion of respiratory complications rapidly increased, pulmonary complications being particularly fatal. Many patients had slumbering or latent nephritis lighted up, and of these the majority died. Post-mortem examination showed evidence of long-standing renal degeneration, both macroscopically and microscopically. Of 3000 men in Captain Charters Symonds's casualty clearing station admitted for influenza, 22 developed renal disease.[1] The epidemic was serious from a military point of view at the time when an attack was expected, but the German Army was also severely affected, whole divisions being withdrawn owing to sickness.

General W. S. THAYER, U.S M.C., of the Johns Hopkins Hospital, said that the American Army had had a similar experience, the epidemic bursting out at several different camps at the same time, and not starting from a single centre. It occurred in a mild form, with a three or four days' fever, no complications, very few respiratory symptoms, and no mortality except in the case of men who had been subjected recently to phosgene gas by the Germans, and who developed pneumonia. In the latter part of September a more severe type broke out, with severe respiratory complications, almost entirely pneumonia, and a pneumococcus pneumonia almost universally. There was a simultaneous outbreak in camps in America, and many men developed the disease on board ship on their way over.

Surgeon-Lieutenant E. L. STURDEE, R.N., gave his experiences at a naval depôt. From July to September the epidemic never quite stopped, and about Sept. 27th there was a sudden rise in the numoer of cases. Deaths almost entirely occurred amongst men of 18 to 20. The pneumonia in the second epidemic seemed to be a secondary and entirely epidemic infection, coming on while the men were recovering, and rapidly spreading from one to another.

Bacteriology.

Surgeon-Captain P. W. BASSETT-SMITH spoke of the Plymouth epidemic, which was associated with pleuro-pneumonia as a secondary infection of a very virulent type, that and empyema being very frequent. Examination of the sputum showed the presence of the Pfeiffer bacillus, the pneumococcus, and streptococcus. The streptococcus was the most virulent organism in that particular locality at this time, but the pneumococcus had been obtained in relatively large numbers from the blood in cases occurring at another port, and either the streptococcus or the pneumococcus might be the cause of death.

[1] THE LANCET, 1918, ii., 664.

General THAYER gave the results of studies of the disease which were collected at the Central Laboratory. In some instances the influenza bacillus was present in the nasal secretion, and in these there were few respiratory complications. Later, as respiratory symptoms became more common, the influenza bacillus was discovered in a larger number of cases than at first. The organism was found in the upper part of the respiratory tract and less commonly in the lung. In certain early cases a small Gram-negative diplococcus had been found. The complicating organism varied. With regard to the respiratory complications, he said that the pneumonia which followed influenza had been with the American Army pneumococcus pneumonia, though isolated instances of streptococcus pneumonia had been seen. In other instances streptococci had occurred in connexion with pneumococci—mixed infection—but in the majority of cases it had been a pure pneumococcal pneumonia. The pneumococcus as found in the camp hospitals was, for the most part, Types 4, 3, and 2; there were relatively few cases of Type 1. There was a great rise in the number of cases of meningococcal meningitis associated with the outbreak, and in several different points in connexion with the pneumonia observed, meningococci had been cultivated from the lung tissue. The general feeling had been that it was a secondary factor.

Investigation of Cases at Royal Herbert Hospital, Woolwich.

Sir KENNETH GOADBY gave an account of the study of a number of acute cases of the prevailing epidemic of influenza in the wards of the Royal Herbert Hospital, Woolwich. About 1000 cases were admitted, with a mortality of about 5 per cent. The majority of the cases were characterised by acute onset of malaise, with pain in limbs and frontal headache. Some of the cases had practically no lung symptoms, but a large number developed an acute broncho-pneumonia, commencing at the base of the lung and associated with blood-stained sputum of a salmon-pink colour; very few showed the rusty sputum common in lobar pneumonia. Epistaxis was a common feature, and a proportion of the cases showed a cyanosis of a curious type not directly attributable to consolidation of the lung. He had made a bacteriological examination of 30 cases at various periods after the onset from the first to the seventh day. Seven cases had consolidation of the lung, 27 had epistaxis, and 27 had broncho-pneumonia with red-stained sputum. A short diplo-bacillus had been found, but not in pure culture. It grew on blood agar only, was Gram-negative, non-motile, extremely short, and showed a tendency in individual cultures to considerable alterations in morphology. Streptobacilli containing 7 or 8 elements and even threads had been noticed, as well as shorter, somewhat swollen forms of an oval clostridial type. The organism corresponded with the description and characters originally given by Pfeiffer, was present in the films of the sputum in 27 cases, and was isolated in pure culture in 18. In addition the pneumococcus and streptococcus occurred with considerable frequency. Gram-positive diplococci with capsules were found in 22 of the sputa examined microscopically, and were isolated in 21. The streptococcus was seen in 14 of the sputa examined microscopically, and was obtained in pure culture in 19; it was strongly hæmolytic. Various types of the Gram-negative cocci of the *Micrococcus catarrhalis* group were observed, and in the last series of cases examined a few showed the presence of Gram-negative bacilli of the Friedländer type. The Gram-negative bacilli of the influenza class were present in greatest numbers in the sputa examined in the early stages of the disease, especially when blood staining first appeared. Blood culture was attempted in 6 cases, 2 of which proved positive, the organism isolated being in both cases the streptococcus of strongly hæmolytic type. No Gram-negative bacilli were found. In the 30 cases examined the bacteriology of the fatal and non-fatal cases appeared similar. The hæmolytic streptococcus was recovered from the sputum of 6 of the 10 fatal cases, and was not present in the remaining 4. A blood examination was made in 8 of the cases, 3 of which were fatal. The outstanding feature was a leucopenia. In no case was leucocytosis observed. In the differential count there was a relative polymorphonuclear leucocytosis in 3 cases, 2 of which were fatal. The recovering case was an extremely grave one, in which a vaccine was used, which might possibly have complicated the issue. A differential count of Arneth's type showed a large increase in the

horseshoe and rod-shaped nuclear cells and a diminution in the trilobed nuclear. There was no appreciable increase in the quantity of large mononuclear or small mononuclear cells, except in 1 fatal case. The high relative proportion of rod-nuclear and horseshoe-nuclear cells appeared of decided prognostic significance. The fact of the occurrence of plasma cells was also striking. Whatever its pathological significance, he thought there was no doubt that a short Gram-negative bacillus was associated with the early acute stage of the present epidemic in all the cases which he had examined.

Account of Another Investigation.

Captain H. E. WHITTINGHAM, R.A.M.C. (T.), attached R.A.F., gave an account of investigations which were undertaken by him and Dr. Carrie Sims to ascertain whether the present October "influenzal" epidemic and the July "Spanish plague" were due to one and the same micro-organism or group of organisms. That the causal organisms were not the same in both cases was suggested by the distinct difference in the signs and symptoms. Pharyngitis and laryngitis, with marked nervous prostration, distinguished the earlier epidemic; bronchitis and broncho-pneumonia, with septicæmia, the plague now with us. Over 100 cases were examined as regards the micro-organisms present in the posterior nasal swabs and sputa. The urine of these cases was also examined on several occasions. Blood cultures were performed on the first 50 of the cases admitted to the two hospitals in which he and Dr. Sims worked, and they had based all their figures on these 50 cases; but taking each case as admitted, whether mild or severe, would give as fair a picture as possible of the pathological findings of the disease. *Blood cultures* were performed on 50 cases. Positive results were obtained in 7 (or 14 per cent.), and of these the streptococcus was found in 5, the pneumococcus in 1, and a Gram-negative diplococcus in 1, this organism being isolated by them twice in the July epidemic. Three of these streptococci hæmolysed distinctly and 2 slightly. Death occurred in 6 of the 50 cases, 4 of the deaths (or 57 per cent.) occurring amongst those patients with a positive blood culture, the other deaths being due to purulent bronchitis and cerebro-spinal meningitis respectively, in which cases blood cultures proved negative. The death-rate among the patients with a negative blood culture was 4 per cent. The day of disease on which the various blood cultures were taken and the results of culture were shown in a table, the percentage of cases showing positive blood cultures increasing as the disease progressed, all cases showing positive cultures on the sixth and seventh days. *Throat swabs and sputum.*—Posterior nasal swabs were examined from the 50 cases, and the sputum of 23 of these. The chief micro-organisms present were as follows: Streptococcus was found in 80 per cent., pneumococcus in 66 per cent., *M. catarrhalis* in 72 per cent., staphylococcus in 54 per cent., *B. influenzæ* in 48 per cent., *B. septus* in 20 per cent., pneumo-bacillus in 16 per cent., and meningococcus in 8 per cent. of the cases. Captain Whittingham then gave a detailed description of the micro-organisms found. Streptococci were the predominant organisms in 30 per cent. of the cases, pneumococci predominated in 26 per cent., *M. catarrhalis* in 34 per cent. (being very similar to those isolated so frequently in the previous epidemic), *B. influenzæ* in 1 case (though found usually in small numbers in many of the cases), staphylococcus in 8 per cent. (most frequently *Staphylococcus aureus*). Meningococci were isolated from the posterior nares in 4 cases; 2 of these developed typical cerebro-spinal fever, 2 failed to show meningeal signs, and were apparently carriers.

Post-mortem examination.—Of the 50 cases dealt with, there were 6 deaths, or 12 per cent. Post-mortem examinations were performed on 5 cases, the pathological findings being more marked in those who died later in the course of the disease. The principal findings were as follows. The trachea showed acute congestion, more marked in the lower part, and in 2 of the cases greenish-yellow pus filled the lumen of the tube. The bronchi were congested, and pus filled them in the 2 cases in which it was found in the trachea. *Lungs.*—In the 2 cases which died on the fifth day there were marked congestion and œdema of both lungs; in the other cases there was double lobar pneumonia. The pleuræ showed inflammation. In 2 cases blood-stained inflammatory exudate was found in both pleural sacs; left unilateral empyema was present in 2 other cases. *Pericardium.*—Sero-fibrinous pericarditis was present in 1 case. In the 4 other cases the pericardium was normal. *Heart.*—In all cases there were more or less dilatation of the right heart, ante-mortem clot in the right auricle and ventricle, and pallor of the cardiac muscle. The *bronchial lymph glands* were enlarged, soft, and congested in 3 of the cases. *Peritoneum.*—Petechial hæmorrhages were found in all the cases; fibro-purulent peritonitis was present in 1. The *liver* showed early fatty changes throughout. The *spleen* was somewhat enlarged, congested, soft, and pulpy in 4 cases. *Kidneys.*—Slight fatty changes occurred in 1 case, 2 showed marked congestion, and 2 distinct toxic nephritis. Stomach and intestines showed submucosal hæmorrhages in 2 cases. *Brain.*—Distinct congestion of meninges and grey matter of the cortex was present in 2 cases. Ventricular fluid was normal in all.

Bacteriological examination of material taken at the post-mortem showed that the *B. influenzæ* was present in the bronchial discharges and lungs of 1 case only. Pneumococci were present in the bronchial discharges, lung smears, and pleuritic fluid of all cases, in every instance accompanied by streptococci and in 2 cases by *Staphylococcus aureus*. On one occasion pneumococci were isolated from the pericardial sac. Streptococci were present in the bronchi and lungs of all cases, in the pleuritic fluid of 4, in the heart's blood and spleen of 3, and peritoneal fluid of 1 case. The cocci conformed to the hæmolyticus type in all except 1 case. Pneumo-bacilli were isolated from the lungs of 2 cases and *Streptococcus aureus* was found in the bronchi and lungs of 2 cases.

Urine.—As in the July epidemic, albumin was present in a high percentage of cases, 100 per cent. on the second day of the disease. Casts and renal epithelium undergoing granular degeneration were present in 50 per cent. on the third to fifth day. Granular casts and renal cells were the commonest, hyaline casts were frequently present, and in some of the more severe cases epithelial and even blood casts were found. On the whole the kidney changes were greater in the present outbreak. The albumin continued to be present over a longer period, in some instances not clearing away before the twenty-first day, and where it had disappeared it often returned when the patient was given an increase of diet or was allowed out of bed. Patients had even returned to duty only to relapse, with distinct albuminuria and œdema of the eyelids. It was of the utmost importance that all influenza cases should be free from exposure to the elements and hard work for at least three weeks after the acute symptoms had subsided.

Leucocyte count.—Daily total and differential leucocyte counts were done on 12 cases over a period varying from 4 to 21 days. The results obtained showed three distinct types of leucocytic curves in the present "influenza" epidemic: Type 1, influenza uncomplicated; Type 2, pneumonic form; and Type 3, the lethargic form. The influenza type showed a total leucocyte count a little below normal in the early days of the disease and a leucocytosis of moderate degree (10,000 to 15,000 per c.mm.) from the fifth to the seventh day. In the pneumonic type there was a distinct leucocytosis (from 15,000 to 30,000) from the onset, and the total white count never fell below the normal unless death occurred, when either a leucocytosis or leucopenia might supervene. In the lethargic form there was an absolute decrease in the leucocytes (2000 to 3000 per c mm.) from the first, which lasted 7 to 12 days. With convalescence the total number of white corpuscles increased (10.000 to 15,000 per c.mm.), but in cases where death took place the leucopenia became more and more pronounced; all the normal varieties of white corpuscles showed an absolute decrease in their numbers during this leucopenia.

The Epidemic at Aldershot.

Captain HALLOWS spoke of his experience of the epidemic at Aldershot, where there were a number of mild cases in June of this year. In these cases he had found a diplo-streptococcus, and from wet swabs of the posterior nares in about 50 per cent. he had found the *B. influenzæ*. During the present phase of the epidemic he had examined about 35 to 40 cases post mortem with Colonel French's help, taking cultures from the spleen, blood, kidneys, and in some cases from the internal ear, and from any other local lesions which presented themselves, and in about three out of four cases got a positive culture from the heart blood. Those cultures were usually a diplo-streptococcus, in a very few cases the pneumococcus, and in fewer still the pneumococcus and the diplo-streptococcus. In 10 per cent. only of cases had he got a culture from the spleen. He had

got no growth from the kidneys or urine, even though albumin, casts or transitional epithelial cells had been found. He regarded the diplococcus as a pathogenic streptococcus, as the dominant organism in causing the complications of this disease—those complications which we regard as being septicæmic, such as capillary broncho-pneumonia or capillary bronchitis. The fact that it was grown from the heart's blood, from the spleen, and from the lung, and many other parts of the body, he regarded as proof of its being septicæmic. He had found in some cases a very definite collection of pus in the sphenoidal sinus, the growth there giving in some instances the *B. influenzæ*, and in all cases the diplococcus. He thought the initial infection was due to *B. influenzæ*, but the diplococcus soon got a hold and became septicæmic, and gave rise to other conditions of the body, the lung condition being purely secondary to the general septicæmia.

Cases on a Transport.

Captain J. G. HOPKINS, U.S.M.C., gave an account of a number of cases which came in entirely from one transport and were divided among a number of different hospitals. As the epidemic went on the pathological findings presented a different picture. In the autopsies on the first series of cases the influenza bacillus was found alone in 13 cases, mixed with other infections in 24, the pneumococcus in 15. Later, in two widely separated hospitals, out of 55 cultures the *Streptococcus hæmolyticus* was found in 33 per cent.; in another hospital, out of 22 autopsies the pneumococcus, Type 4, was found in 22, or 100 per cent., and the streptococcus in 4 per cent. In other words, though the original infection was in all cases the same, yet in one hospital there was a preponderance of cases infected with *Streptococcus hæmolyticus*, whereas in another there were 100 per cent. of cases with the pneumococcus. They concluded that the pneumococcus, the streptococcus, the staphylococcus, and meningococcus were probably secondary infections. Whether the influenza bacillus was the primary cause or also a secondary invader it was difficult to determine, but we had to bear in mind that these bacterial infections were superimposed on one another.

Major LITTLE, Surgeon-Lieutenant G. ROCHE LYNCH, R.N., Captain ARCHIBALD MALLOCK, C.A.M.C., and Captain W. E. CARNEGIE DICKSON also spoke on the bacteriology of the disease.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

A MEETING of this section was held on Nov. 7th, Mr. J. D. MALCOLM, the President (and later Dr. AMAND ROUTH), being in the chair.

Presidential Address.

The PRESIDENT, in his address, reminded his audience of the methods of the followers of Lawson Tait, who administered purgatives soon after the operations and forbade the giving of opium, but who scoffed at the germ theory and the use of carbolic acid. Their fatalities, he said, were chiefly from septic peritonitis. If they had brought their new methods into harmony with Lister's teaching they would have advanced almost at a bound to our modern technique and would easily have shown a superiority over the methods practised by the followers of Lister. But they missed a great opportunity. In 1884, said Mr. Malcolm, operations were hardly ever undertaken when acute inflammatory conditions existed, but now a great part of our work was essentially preventive. Operations anticipating complications were extraordinarily successful, especially in connexion with intestinal work. The principle of anticipating trouble had been introduced into the war surgery of the abdomen with great advantage to the patients. The death-rate from abdominal operations at the Samaritan Free Hospital had been reduced from 14 per cent. in 1884 to less than 4½ per cent. in 1916 (the last year available), and this although the area of operative work was much larger and more dangerous in recent years. Finally, it was urged that as hostilities would soon cease the section should endeavour to throw off the inertia which had overtaken its work as a consequence of the war and should resume its meetings regularly every month.

Treatment of Ante-natal and Post-natal Syphilis.

Mr. JOHN ADAMS said that the Local Government Board had made an order that the Metropolitan Asylums Board should arrange with the City of London guardians to receive and treat parturient women suffering from venereal disease, the actual cost being made a charge on the metropolis generally; and, as a result, the Thavies Inn Venereal Centre for Pregnant Women was equipped and opened on Sept. 1st, 1917, and a matron, sister, nursing staff, and himself as medical officer in charge were appointed. The institution provided for 20 beds, and contained an accouchement-room and an operating theatre; it was managed by the guardians of the City of London, who took a keen and progressive interest in its working and results. Since its opening 30 cases of pregnant syphilitic women had been admitted. He gave a detailed account of each case, including the details of the treatment before and after delivery, the treatment of the baby, and the results, as far as they could be ascertained, during the short time the centre had been opened.

On admission a Wassermann test is made by Dr. A. E. Stansfeld, of St. Bartholomew's Hospital, on the blood of every patient suspected of suffering from syphilis, and recently he had had the test made in every case admitted. Immediately on the birth of the child the Wassermann test is done on the blood of the mother, and on that obtained from the vessels of the divided umbilical cord, and a portion of the placenta is examined for spirochætes. As soon as syphilis is diagnosed in the mother weekly doses of the salvarsan substitutes are administered intravenously, beginning with a small dose and increasing till nearly the maximum dose is reached; intramuscular injections of grey oil, 40 per cent. B.P.C. emulsion, are given in 1 g. doses on the same day as the salvarsan. Galyl and novarsenobillon are used, galyl in glucose solution exclusively for the babies. He considered mercury extremely important for the cure of syphilis, and thought that administration by the mouth (as a pill of hyd. c. cret. with equal parts of pulv. ipecac. co., as advocated by the late Sir Jonathan Hutchinson) was the most convenient method, especially in the case of patients who could not be under continual supervision. He preferred galyl to novarsenobillon, and had once had a case of severe dermatitis whilst using the latter drug. He calculated the dose of galyl for a baby by comparing the babies' weight with that of the mother, of which it is about 1/17, so that he gave the babies an intramuscular injection of galyl in doses beginning at 2 cg. and increasing to 5 cg., and mercury in doses of ¼ to ½ gr. or more. The intramuscular injections were given anywhere along the middle third of a line drawn from the anterior superior spine of the ilium to the commencement of the gluteal fold, and the mercury and galyl could be given the same day on opposite sides and repeated after an interval of a week to 10 days.

Reviewing the cases, he said that out of 30 cases 6 babies had been born free from any evidence of syphilis, having a negative Wassermann reaction at birth which continued on future examination of the blood, although the mother had still given a positive reaction for a considerable time after delivery. It had been found that those babies who had at first a positive reaction generally yielded a negative reaction after treatment sooner than their mothers. Up to the present he had not found any case in which a baby who had become negative had later developed a positive Wassermann reaction. The average number of doses of galyl required to bring about a negative reaction had been 6·5, and the amount per case 30·15 cg. In every instance it had been found that the child gained regularly in weight and showed no further signs of syphilis. Owing to the limitation of accommodation at Thavies Inn cases could not be admitted before the sixth month of pregnancy. He was of opinion that with a large hospital and earlier treatment fewer syphilitic children would be born dead, a larger proportion of them would go to full term, and if not free from syphilis at birth they could by treatment soon become so.

Mr. Adams's conclusions were as follows: 1. Syphilitic pregnant women could be treated with salvarsan, even up to the day of their confinement, with every advantage. 2. A mother whose blood gave a positive Wassermann reaction might, after treatment, be delivered of a child whose blood gave a negative reaction. The child might continue to thrive and give a negative blood test. 3. Syphilitic children could safely be treated by salvarsan immediately after birth. 4. Salvarsan, combined with treatment by mercury, had a more certain and quicker action in producing a negative Wassermann reaction in the child than in the mother. 5. In nearly all syphilitic children born

alive, treatment could convert a positive Wassermann reaction into a negative, and such children appeared to become healthy and showed a regular weekly gain in weight. Between a syphilitic mother and a child who gave a negative Wassermann reaction at birth the placenta appeared to act as an intercepter of syphilitic virus, probably brought about by the chorionic ferments, as shown by Dr. Amand Routh.[1]

Discussion.

Dr. AMAND ROUTH said that according to the Johns Hopkins Hospital reports, apart from deaths at labour due to complications, 25 per cent. of stillbirths were due to syphilis, and amongst illegitimate babies double that number. He was struck by two important things: (1) how it was that any child infected at fertilisation was born alive; and (2) that a number of cases of children of syphilitic mothers stood a good chance of being born healthy. It seemed that there must be some force controlling pregnancy, and from the beginning of pregnancy to childbirth he believed that the chorionic ferments did produce something which could control the situation to some extent. They were no doubt scattered throughout the mother's body and rendered her immune from active propagation of spirochætes during pregnancy. Women after many pregnancies might become cured of syphilis. He had seen cases of this kind in which a mother had first a miscarriage, then a stillborn baby, then a full-term infected child, and later children who showed infection some time after birth.

Mr. W. G. SPENCER remarked on the value of in-patient treatment, which should be increased so that very active treatment could be given in a way which was impossible in out-patient practice. The two medicines must be used, the one which got rid of the manifestations, and the other which got rid of the disease.

Dr. M. HANDFIELD-JONES asked what care should be taken of women in subsequent pregnancies. He had known of a case in which the woman had given birth to a macerated fœtus. She was treated with mercury during the second and third pregnancies. At the fourth pregnancy she was considered cured and was not treated, but at the eighth month movements stopped.

Captain W. GIRLING BALL said that the great difficulty was to get syphilitic mothers early enough. Cases were treated from the sixth month, but more prolonged treatment ought to have better results on the child. A negative Wassermann reaction was produced after 12 doses of salvarsan and mercury in the majority of cases, and in many after six doses. We could never get rid of syphilis if out-patient treatment only were available. Men were more irregular than women in attending. It was waste of these expensive drugs if treatment was not carried out as advised. A large central institution was needed.

Dr. W. H. KELSON said it was necessary to follow up results, especially as regarded future pregnancies.

Dr. A. E. STANSFELD drew attention to the short time in which the Wassermann reactions changed from positive to negative in Mr. Adams's cases. This was not noticeable in older children, and showed a good case for prolonged treatment of babies after birth.

Mr. ADAMS briefly replied, and remarked that if babies were treated early enough (at the latest on the second day) there was no secondary eruption.

SECTION OF ELECTRO-THERAPEUTICS, CLINICAL SECTION, SECTION OF MEDICINE, AND SECTION OF SURGERY.

Examination of the Vermiform Appendix by X Rays.

A MEETING of these sections was held on Nov. 15th, Mr. CECIL R. C. LYSTER, the President of the Section of Electro-Therapeutics, being in the chair.

Dr. E. I. SPRIGGS read a paper on the Examination of the Vermiform Appendix by X Rays, and showed photographs and drawings by Mr. O. A. Marxer, radiographer, Duff House. After a summary of the literature of appendix radiography, in which indebtedness to American workers was acknowledged, a description was given of the methods found of value. The patient was prepared with castor oil and given a meal, similar to that recommended by George and Gerber,[2] consisting of ¾ of a pint of buttermilk and 150 g. or less of barium sulphate. Careful screening with suitable manipulation was needed to observe the mobility of the appendix and the presence or absence of active movements or of tenderness. Photographs must also be taken freely, as the chief points which helped to decide whether the appendix was healthy or diseased—namely, the filling and emptying of the appendix, its position, and its outline—are observed best on the photographic plates. The manipulations which had been found most useful were detailed. The following figures were given. The first hundred cases in which was observed the passage of an opaque meal through the alimentary canal were left out of account, as the ileo-cæcal region was not examined with such care as is now given to it. Of the next two hundred cases, with a standard meal, in many of which castor oil was also used, the append x was seen clearly in a few. Then was begun the use of the barium and buttermilk meal after preparation by castor oil. In the fourth hundred cases the appendix was seen 24 times; in the fifth hundred 35 times; then 54 times; then 72 times; and in the eighth and last hundred 86 times. An account was next given of the radiography of the normal appendix, and photographs were thrown on the screen. The paper then described the examination of cases of appendicitis. In acute appendicitis the patient was not usually fit to be X rayed, neither was such a method of diagnosis needed. In chronic appendicitis X ray examination had been found of great value, especially in the subjects of vague abdominal symptoms of unknown cause. In 36 cases a diagnosis of chronic appendicitis had been made and confirmed by operation. Radiograms of many of these were shown, accompanied by coloured drawings of the appendixes after removal. The chief points to which attention should be paid were: 1. The filling and emptying of the appendix; delay. 2 Shape; constriction and dilatation. 3. Fæcal concretions; vacuoles. 4. Mobility. 5. Hyperactivity; spasm. 6. Tenderness. 7. Position. These features were placed in the order of their importance in a series of cases. Each was illustrated by lantern slides and clinical details. The signs of present inflammation were, in addition to pain and other clinical symptoms: a tender point (though tenderness required care in its interpretation) and varying dilatation of the lumen from hyperactivity and spasm; whilst evidence of former disease, recent or remote, was given by concretions, abnormal outline, delay in filling or emptying, adhesions, severe kinks, and, in certain cases at least, by the absence of a shadow. The proportion of cases in which no barium sulphate entered the appendix was small when the methods described were used; but it was not thought justifiable in the present state of our knowledge to assume that an appendix was abnormal because it did not fill, though it should be regarded with suspicion, especially if the observation were repeated. The paper was founded on the study of the photographs of about 300 appendixes.

Mr. A. C. JORDAN discussed the paper briefly, and showed some photographs of appendixes in a few of his own cases.

A CLINICAL meeting of the North London Medical and Chirurgical Society was held at the Great Northern Central Hospital on Nov. 14th, Mr. Arthur Edmunds, the President, in the chair. Dr. Alexander Morison and Mr. Fred. Stoker presented medical and surgical matters for discussion. There was a considerable attendance of North London medical practitioners.

IRISH OPHTHALMOLOGICAL SOCIETY.—The opening meeting of this society was held in Dublin on Nov. 8th, after the Montgomery lecture by Dr. Euphan Maxwell, Mr. James Craig (Belfast) being in the chair.—The rules were drawn up and adopted and the following were elected to hold office for one year:—President: Mr. A. W. Sandford, Cork. Council: Mr. J. B. Story, Mr. L. Werner, Mr. J. A. Craig, Mr. H. C. Mooney, Mr. F. H. Crawley. Honorary secretary and treasurer: Lieutenant-Colonel T. H. Delany, I.M.S. (retired), 29, Upper Fitzwilliam-street, Dublin.—Mr. Werner exhibited lantern slides of a case of Cysticercus published in the Transactions of the Ophthalmological Society of the United Kingdom, vol. xxiii., p. 193, and Mr. Story exhibited charts of Fields of Vision in Glaucoma.—Next morning patients were shown at the Royal Victoria Eye and Ear Hospital, amongst others, a patient whose case was published in the Transactions of the Ophthalmological Society, 1891, p. 127, of detachment of the choroid; also two cases of fat implantation, one in Tenon's capsule and the other in the sclerotic after evisceration, the eye in each case being buphthalmic.

Reviews and Notices of Books.

War Surgery from Firing Line to Base. By BASIL HUGHES and H. S. BANKS. London: Baillière, Tindall and Cox. 1918. Pp. 623. 33*s.* net.

A BOOK such as this will serve as an excellent record of the work as carried out by the men who wrote it and of the method that they have chosen as the best for dealing with the wounds of war. The authors have had a considerable experience in war surgery both in France and Salonika, and as a result thereof have come to the conclusion that the best method of obtaining a rapid sterilisation of wounds is by the Carrel-Dakin method, thus allowing of the performance of secondary suture with the consequent early restoration of function of the part affected. They are insistent, and quite rightly, that in order to obtain good results the method should be rigidly carried out after the fashion originally described by the originators. The authors have been fortunate in being able to organise their methods in a given area from the firing line to the base, and thus maintain a continuity of treatment which is not often possible in many of the theatres of war. Under these conditions it is interesting to find that the results that they have obtained correspond to those of others who have adopted the same methods; there are so many difficulties in carrying out the treatment efficiently, combined with the large amount of bacteriological investigation necessary, that the authors are to be congratulated on the results of their efforts. It is with these methods, as applied in their hands to lesions in various parts of the body and in different areas of fighting from the firing line to the base, that this book is largely occupied, and the description is done well.

It is a little disappointing to find, however, that so little attention has apparently been paid to the methods of primary and delayed primary suture, which have so largely supplanted the necessity of secondary suture during the last two years of the war. These methods are coming to the fore as results become better known, and in a book such as this the newest line of treatment should be encouraged. There is also a tendency to decry the value of certain drugs, such as flavine and bismuth-iodoform paste, which in the hands of many have met with considerable success. These are details, however, as compared with the general principles which are laid down and well described in this book. Considering the great difficulties under which the authors must have laboured, far away from books of reference and skilled artists, the production of this work has many remarkable features.

The illustrations, mostly photographs, are numerous and topical; it is a little difficult to account for the comic element displayed in certain coloured drawings, unless it is to remind the surgeon of the wonderful manner in which the soldier puts up with the manipulations that he is compelled to undergo at our hands and the trials that he has to pass through in tropical climates. We should add that the humorous effect is happily obtained. The experience of the authors is emphasised by the description of the methods of treatment of all kinds of wounds in the various fields of warfare, firing line, field ambulance, C.C.S., and base hospital. And to those accustomed to work in France the completeness of the experience with regard to wounds in all parts of the body as embodied in the text will seem remarkable. Not only is the general technique of the treatment of wounds by the Carrel-Dakin method carefully detailed with regard to wounds in general, but its application to wounds of the head, chest, abdomen, bones, and joints (the latter an excellent article) is minutely gone into. Naturally the effort is unequal, but for the most part the principles are sound. Was it necessary to include in the volume a condensation of a text-book on bacteriology? This section, however, will serve a purpose in making complete a book which is the only volume of its size dealing with surgery such as we know it in this war, and will complete a *vade mecum* to those unfamiliar with the methods described.

The Canadian Medical Week. Published under the auspices of the Ontario Medical Association. Toronto: The Macmillan Company of Canada, Ltd. 1918. Pp. 338. $3.00.

THIS stately volume is a worthy record of the Canadian Medical Week, held at the beautiful city of Hamilton, on Lake Ontario, from May 27th–June 1st last. It is dedicated to the graduates and undergraduates in medicine of the Canadian universities who have fallen during the war, and on the frontispiece is printed Colonel John McCrae's haunting poem, "In Flanders' Fields." Physicians from every part of Canada and from the United States attended the gathering and discussed many of the burning issues of contemporary medicine. Dr. L. F. Barker's address on the Significance of Heart Murmurs in Recruits, Dr. R. A. Bolt's paper on the Education of the Medical Student in his Relation to Child Welfare, and Dr. T. H. Ames's contribution to the Prevention of War Neuroses, as well as others in the volume, merit a wide circulation. It is noteworthy that the book only contains advertisements "censored by a Special Committee appointed for that purpose."

Anatomy: Descriptive and Applied. By HENRY GRAY. Edited by ROBERT HOWDEN, M.A., D.Sc. Twentieth edition. London: Longmans, Green and Co. 1918. Pp. 1324. 37*s.* 6*d.*

"Gray's Anatomy" maintains its popularity in the hands of its present editor, only 18 months having elapsed since the appearance of the previous edition. About 60 new illustrations have been added and the text is carefully revised. To remind readers of the original author, a short biography of Henry Gray, F.R.S., F.R.C.S., 1827–1861, is given, as well as the names of later collaborators: Timothy Holmes, T. Pickering Pick, and, finally, Professor R. Howden, with his two associates, A. J. Jex-Blake and W. Fedde Fedden. The new terminology, introduced in 1913 with the eighteenth edition, is retained presumably until a terminology satisfactory to English-speaking anatomists has been formulated. To this end coöperation with anatomists of America and of the Dominions is most desirable. In the meantime, for the sake of the perplexed student, the old terminology is inserted in brackets and both sets of names are indexed.

JOURNALS.

Military Surgeon (Washington, D.C., U.S.A.).—The issue for September has the first instalment of an article on Communicable Diseases in the U.S. Army, by Colonel V. C. Vaughan and Captain G. T. Pratt of the U.S. Army. The principal acute diseases which occurred last winter in the Army in the United States, in the course of which respiratory symptoms were seen, were pneumonia, meningitis, measles, scarlet fever, and diphtheria. Pneumonia stands out with a sinister pre-eminence. It caused 60 per cent. of the total deaths, meningitis 12 per cent., measles 1·1 (but many of the pneumonias followed measles), scarlet fever ¾, and diphtheria ½ per cent. Deaths from pneumonia were more frequent than usual among the civil population during that hard winter, but the death-rate in the Army (ages 20 to 30) was ten to twelve times that in civil life at the same ages. Men from rural communities and men from the South were found to suffer most, because, it is suggested, they are less immune to "crowd" bacteria, which flourish among the denser populations, who therefore grow up with an acquired immunity, a theory which gains support from the accurate observations of Dr. J. W. H. Eyre and Captain C. E. Lowe on New Zealand troops in THE LANCET of Oct. 12th. As to prevention, vaccination is asked for, and no reference is made to Colonel Munson's report on the prophylactic value of ventilating tents in the preceding winter amongst the U.S. troops in Mexico. "Baith is best" is an old Scots proverb, and though we trust antityphoid vaccination, we yet strive to give men always clean water.—There is a long paper by Captains W. E. Lee and W. H. Furness, U.S.M.C., on the Evolution of Dichloramine-T as an Antiseptic in Wound Treatment. At the beginning of the war, they say, aseptic primary closure of wounds was attempted, but gas gangrene and other infections occurred so frequently that that procedure was forbidden. Then surgeons tried antiseptics of all sorts—salt packs, flavine, the Reading bacillus, "last and least of all, soap and water," and all this time military arrangements were improving, so that the wounded came more quickly under treatment and the technique of that treatment also improved, so results became wonderfully better. In 1916 wounds were being excised, for it had been realised how much tissue around a wound had been contused to death by the mechanical injury. Besides that, projectiles and fragments of clothing are apt to be infected, and must be removed to prevent harm, so also must splinters of bone or cartilage, severed from their blood-supply, dead, and now only a ready nidus for bacterial growth. Thus the gas bacillus lives and grows in dead muscle. Even with excision not all sepsis can be excluded. If an ordinary wound is treated within three hours so little bacterial growth has occurred that the wound may be safely closed, the tissues being able to deal with the few germs there are.

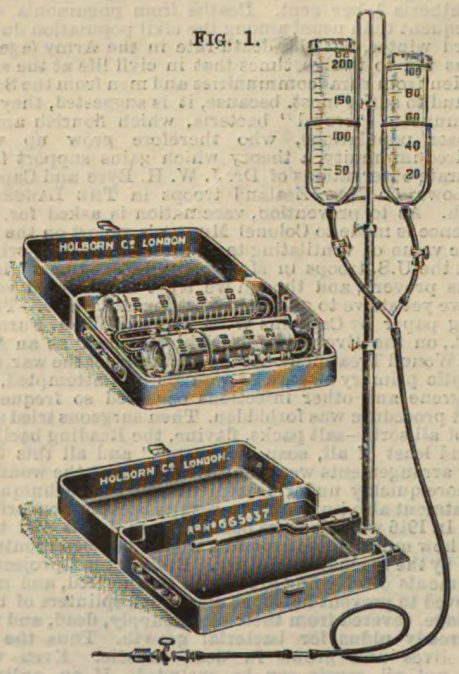
Hence the need for speedy first-aid organisation. After three hours the wound will require some antiseptic. The authors have worked with Dakin's solution introduced by Carrel, who found the extreme of surgical care insufficient unless assisted by an antiseptic. The original antiseptic being Labarraque's solution, it was found, however dilute, gravely to irritate the skin, so Dakin made a neutral solution with 0·5 per cent. chlorine equivalent, which did not irritate the tissue cells but inhibited bacterial growth. This neutral solution was very unstable, so had to be prepared daily. It had a weak antiseptic value, soon passing off, and had to be applied to the wound therefore in quantities frequently. Carrel and Dehelly devised the system of containers and tubes which require care, time, and money. In answering the question why the skin was irritated but not the raw surface, it was found that the chlorine with the proteids in the serum of the wound formed amines, which further research showed could be synthetically prepared, would act as well as the hypochlorite and would not irritate the skin. Chloramine-T was the first of these, a dichloramine from toluol. It is soluble in water and so becomes diluted in the discharge. Dichloramine-T, however, is only soluble in oils and persists longer in the wound as an antiseptic. A suitable oil solvent was hard to find; eucalyptol was used, chlorinated to prevent it from decomposing dichloramine-T, but chlorcosane (a chlorinated paraffin wax) makes a more stable solution, 5 per cent. to wounds, 2 per cent. for throat and nose sprays. It is decomposed by water or alcohol or exposure to light, but keeps well in dry brown bottles in the dark. 19,000 cases have been treated with this in the United States in the last 18 months with every satisfaction. Burns and open wounds are covered with a single layer of mosquito netting soaked in dichloramine-T paraffin wax, whose open meshes permit discharges to pass through into a couple of layers of sterile gauze laid over it. These are changed when required, the paraffined mosquito-net probably after a week. No bandages cover the surface, and cages keep the bedclothes off. But it is the first essential that the case shall be treated as an operation case from the first, and that no precautions of the antiseptic technique be omitted at subsequent dressings. Dichloramine-T is also recommended as a deodorant in malignant ulcerations, and so used gives great satisfaction in the Oncological Hospital in Philadelphia.

New Inventions.

A PORTABLE "606" OUTFIT.

FOR the administration of "606" outside an institution where this work is routine the usual apparatus is rather

FIG. 1.



inconvenient, being bulky and difficult to pack into a handbag. In addition to these disadvantages the setting up of the apparatus usually takes an amount of time which cannot well be spared, and for casual work of the kind mentioned the surgeon is apt to prefer "914," which can be given with a Record syringe but, given intravenously, is not so permanent in its effects. In order to overcome these disadvantages I have devised an apparatus that can be made much more portable on the lines suggested in Fig. 1, and the whole outfit is contained in two boxes which can easily be slipped into an ordinary surgical bag and set up at the bedside in a few minutes.

FIG. 2.

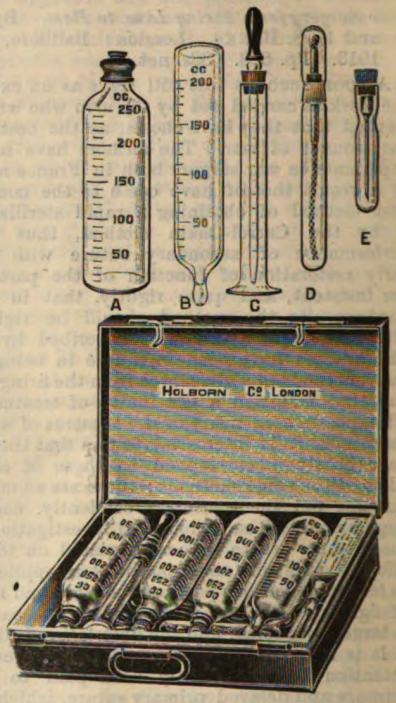


Fig. 1 shows a "6 6" and saline funnel, such as is used in military hospitals suspended on a frame carried on a telescopic stand which is screwed into the hinged end of the box. The funnels are set up at home with the straining gauze in position at the top of each and the rubber tubing attached. The stand is collapsed and the whole turned into the box, which is closed and sterilised in a steamer. At the bedside the box is opened and its hinged end carrying the apparatus turned down and fixed in position by two sliding bars in the bottom of the box. The telescopic stand is then extended to its full length and the apparatus is ready. The other box (Fig. 2) contains, A, three Soxhlet bottles of 250 c.cm. capacity fitted with Eyre's special rubber caps which are designed to permit of sterilisation without the necessity of opening and closing the bottle; one of the bottles is graduated and is used for mixing purposes, the other two are for saline; B, two spare funnels; C, a cylinder with foot, fitted with a graduated pipette and containing caustic soda solution; D, an iodine pencil as devised by Major C. F. White for sterilisation of the puncture site; and E, two needles in alcohol. In the remainder of the space are packed ampoules of "606," a small dressing, and a tourniquet. A, B, and C are sterilised in a steamer and, thanks to the special caps on A, these can be carried quite safely in the box provided. The "606" is mixed in the graduated bottle, which should contain about 50 c cm. sterile distilled water, the cap being removed, the powder poured into the water, and the cap replaced for shaking. The soda is then added to alkalise and the necessary amount of saline to bring to the required dilution, leaving enough saline for the saline funnel.

The apparatus is made by the Holborn Surgical Instrument Company, London.

L. W. HARRISON,
Brevet-Colonel, R.A.M.C.
Rochester-row.

GUY'S HOSPITAL: MEDICAL RESEARCH FELLOWSHIP.—A fellowship, to be known as the "Hilda and Ronald Poulton Fellowship," has been founded at Guy's Hospital in memory of the late Lieutenant Ronald William Poulton Palmer, B.A., Royal Berkshire Regiment, the International Rugby footballer, killed in action in Flanders on May 5th, 1915, and of his sister, the late Mrs. Emily Hilda Ainley Walker, who died in August, 1917. The object of the fellowship will be to investigate the origin, progress, treatment, and cure of obscure diseases in man; its annual value will be £150. It may be held simultaneously with a teaching post at the medical school, with the condition that the fellow devotes at least half his time to research.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 23, 1918.

The Work of the Medical Research Committee.

THE end of the war marks an epoch in the work of the Medical Research Committee set up under the National Health Insurance Act of 1911. The Committee did not actually come into being until September, 1914—that is to say, the end of the first month of the war—and its fourth annual report, which we have before us, therefore comes at the end of the fourth year of war. The Committee has so far lived under exceptional conditions. But, while the war has closed, the Committee's work goes on, and not the least interesting part of the report is its concluding paragraph in which the conditions of peace and war are compared. It is only long familiarity which has deadened our sense to the volume of avoidable suffering and economic loss arising from disease in civilian life, and the Committee justly counts this volume of suffering in the same order of magnitude as the appalling casualties and diseases of warfare. The Committee looks forward eagerly in the report to the ending of hostilities and to the opportunity which will then arise of bringing State resources to the assistance of medical science as a whole. But at the same time an optimistic note is struck in regard to the lessons learned during the four terrible years which are past. The violent disturbance of the peaceful course of scientific work has not been without compensation. Only during the war has the principle gained general acceptance that action to be effective requires guidance in the light of knowledge gained by scientific inquiry. The service of bacteriology to medicine was well recognised before the war, and it has continued throughout the war to rise in esteem, yet physiology during the same period may be said to have found itself—or rather to have obtained immediate and practical objectives. The physiologist has brought his knowledge to bear upon the urgent needs of warfare. The names and constitution of the various special committees, dealing with such wide subjects as shock, chemical warfare, air problems, industrial fatigue, which we take the opportunity of printing on another page, are the best testimony to this fact. These special committees have been largely in the nature of round tables at which discussion on methods has elicited mutual criticism and help. Defects have been promptly cleared up by frank discussion instead of by lengthy argument or polemic in print. Some may think that in avoiding the washing of dirty linen in public these committees have also concealed from their medical brethren the interesting stages by which results have been reached, but of the value of the final results no one can stand in doubt. The work of these committees is analogous to that of certain informal clubs composed of young medical men keen on problems whose pursuit was not bringing material reward. Such clubs were in existence before the war, and they have been too few among us.

But the research work planned by the Committee to bear upon the welfare of the civilian community has, of course, suffered, and suffered grievously in its four early years of existence. Nevertheless, in two directions at least—namely, tuberculosis and rickets—this work has gone on during the war, although in decreased measure. Dr. J. BROWNLEE'S study of the epidemiology of phthisis has recently been completed and issued as Special Report No. 18, and the work of the committee on the relation of phthisis to particular occupations has been taken up again, and will soon form the subject of a further report, of which Professor B. MOORE'S contribution to THE LANCET of Nov. 9th may be considered as an advance instalment. A report upon the influence of social conditions on rickets has already been summarised in our columns, while Dr. E. MELLANBY has continued his studies of the dietetic factors which play a part in its production. This work also is now ready for publication. We hope that the 1914 programme may soon be resumed in its entirety and in more favourable circumstances.

Even an incomplete summary such as this of the work of the Medical Research Committee cannot conclude without an expression of heartfelt satisfaction at the establishment of a *Centralblatt*. The Medical Supplement of the Official Review of the Foreign Press is its present cumbrous title, and the first number, which appeared on the opening day of the present year, was felt to supply a want patent to every scientific worker in medicine. Distributed at first among military hospitals and laboratories, the Medical Supplement was soon issued for sale by H.M. Stationery Office, and no one who has had an opportunity of comparing the abstracts with the original articles can fail to be struck by the fairness and the ability with which the work has been done and by the absence of that tendentiousness which is incompatible with the true scientific spirit and which has estranged so many from the *Centralblatt* on the German model. At the same time, the Committee permits itself to observe with satisfaction that no striking gains in our knowledge or in our methods appear to have come to us from enemy sources. Although we have been modestly willing *ab hosti doceri* the gain in alleviation of the sufferings of war seems to have been largely on the other side. Possibly the enquiry into the epidemiology and bacteriology of influenza, abstracted on another page of our present issue, may have its practical lessons for us. This work of the Medical Research Committee is, we think, likely to develop as time goes on, especially in view of the facts that under the terms of the Ministries of Health Bill the Committee's work will be carried on directly under the Privy Council and that the Committee itself proposes to work in close coöperation with the Advisory Council of Scientific and Industrial Research established in 1915.

The Medical Parliamentary Committee.

A MEETING of the medical profession was held at Steinway Hall, London, on Oct. 1st, having for its object the acquiring of more adequate representation of the medical profession in Parliament. The meeting, the proceedings at which were reported in THE LANCET, was summoned informally and was well attended. Sir HENRY MORRIS, who presided, set out the various arguments for believing that the time had arrived when the medical profession should take steps to show its corporate value to the public and the State through the presence in Parliament of competent members of the profession. Mr. E. B. TURNER followed with an eloquent exposition of the influence that the doctor must have with the public when setting out in plain terms the real meaning of medicine and the aims of scientific pathology. Dr. CHRISTOPHER ADDISON, Minister of Reconstruction, moved at the meeting a successful resolution to the effect that "in the interest of national health it is essential that the considered views of the medical profession should be voiced by representative medical men in the House of Commons." A desultory debate followed, when a committee was formed by the meeting, having a general mission to consider the claims of medical men for election to the House of Commons. It was agreed that this committee should report at a later stage to the whole constituency upon any steps taken. The constitution of the committee, as indicated in our report of the proceedings of the meeting, included representatives of the British Medical Association, but in deference to the views of the Council of the Association, such representation has now been withdrawn.

Several meetings of the committee have been held, the proceedings at which will be laid later before a general meeting of the medical profession; but it seems right that the gist of the work done should be published without further delay, having regard to the fact that a General Election is upon us. The committee, now known as the Medical Parliamentary Committee, has consequently provided itself with the names of medical men who are already willing to place themselves at the immediate disposal of the Whips in the unforeseen event that between now and Dec. 14th any one of these doctors may be adopted as an official candidate for a seat. It is, of course, extremely unlikely that this contingency should occur, as in those localities where elections are being fought the contesting parties have long ago chosen their champions. Moreover, it is easy to see that the names which the Medical Parliamentary Committee may be able to send in to the Whips must constitute a short list, for few medical men who could have a chance of being selected by the Whips to fight even an off-chance will be found able to lay their professional interests aside at a moment's notice and plunge into the whirl of a contested election. The work done by the Medical Parliamentary Committee must be considered merely preliminary, although the slight chance of some immediate accomplishment has been prepared for. What the Committee requires now is, first, adherents to the movement; and, secondly, a list of medical men who at future elections will be willing to place themselves at the disposal of Party Whips to contest constituencies. The introduction of the word "party" will make all medical men wince, but it should not make them stand aside from an effort to do public good, for the Medical Parliamentary Committee professes to make an organised attempt to give the opinions of the medical profession a right influence in public affairs. The medical profession agrees that it requires a louder and clearer Parliamentary voice; it must also agree to obtain that voice in accordance with prevailing customs. No man will get into Parliament on his medical claims. And from our point of view the ideal medical man in Parliament should not represent medicine only; he should be the interpreter of medical thought and aims to his fellow legislators. This he can easily be while assenting to a general party creed, provided that in every word that he utters, and in every idea that he supports, the predominant claims of national health are obvious. Such a legislator can conform to party politics and can keep his necessary pledges to his constituency and to his political organisation, while remaining faithful to ideals outside and above such pledges; and his presence in Parliament upon such terms might be a great destroyer of the evil influence of party. For granted that the health of the people is equally wanted by all political divisions and subdivisions, the medical man in Parliament who, while belonging to a party, was known to place the general weal above the party tactics would be an excellent type to imitate. The democracy of the future is sure to make increasing use of special knowledge directed to generally benevolent ends, while setting a decreasing value upon political machinations. The doctor in Parliament, as we have drawn him, fits such a picture exactly.

At the meeting at Steinway Hall Sir WATSON CHEYNE indicated how useful it would be to such members of the medical profession as happened to be in Parliament if a considered view of medical questions were placed at their disposal by an authoritative body. The Medical Parliamentary Committee by the strength of its adherents should grow into such a body, and we can conceive its utility to the nation as thus becoming something very large indeed. No individual Member of Parliament, even though a medical man, can possibly follow the operations of an elaborate Bill as it may affect the medical profession directly, and therefore as it may affect the whole of the country indirectly. He wants counsel, as Sir WATSON CHEYNE suggests, and a Medical Parliamentary Committee on which there sat men, medical Members of Parliament among them, who could assemble, codify, and articulate a real medical view upon general questions at issue, would be of the first value to the country. In an interesting article which appeared in the *St. Bartholomew's Hospital Journal* for September Sir WILMOT HERRINGHAM, himself a candidate for Parliamentary honours, speaks of the medical Members of Parliament forming themselves

into a private committee. Such an advisory board might be of no great weight scientifically—for no man, to repeat ourselves, can enter Parliament on his medical claims—unless reinforced from without. But from a Medical Parliamentary Committee, such as could be formed if all medical men would help in its promotion, the medical advice would be of the highest worth. Now to constitute a Medical Parliamentary Committee of this order will need the coöperation of all the medical profession, whose powers should be set in action from as many directions as possible. The Parliamentary Elections Committee of the British Medical Association will, we trust, be willing to join a movement whose main objectives must be identical with their own, and which by the elasticity of its constitution can enter into wide public relations while retaining the essential medical spirit.

Annotations.

"Ne quid nimis."

THE WAR CASUALTIES.

Mr. Macpherson, Under Secretary for War, made a statement on Tuesday last in the House of Commons concerning the British casualties in the war, including Dominion and Indian troops. The figures, which were up to Nov. 10th, 1918, are necessarily incomplete, but the totals for all theatres of war were given as follows:—

	Officers.	Men.
Killed (including died from wounds and other causes)	37,876	620,828
Wounded	92,664	1,939,478
Missing (including prisoners)	12,094	347,051
Totals	142,634	2,907,357
Grand total	3,049,991.	

An analysis of these terrible totals will be found in our Parliamentary report.

REHABILITATION OF THE DISABLED SOLDIER IN THE U.S.A.

A SYSTEMATIC attempt is being made in the United States of America to rehabilitate their soldiers who have been disabled in action in the European war "to the point of maximum functional restoration, both mental and physical." An educational section in the office of the Surgeon-General of the American Army supplies the means to enable every returned soldier to add to his knowledge, technical or general, so that on return to civil life he will have at his command the necessary mental equipment to carry on. The section is in close touch with the medical and surgical staffs of the general hospitals. The medical staff is able to indicate the muscular re-development desired and to supervise the restoration of function, so that excessive strain may not provoke harm. At the same time the educational director and his assistants fire the patient's ambition, show him what he can do, explain the means of doing it, and lead him step by step to the finished product of his mind or hand. There are four main groups in this Educational Service. One centres on the problem of preventing a disabled soldier from training for a job which his qualifications and aptitudes do not meet; it seeks to stop him from aiming too high or too low. Another provides instruction in elementary, high school, and professional subjects. In the third group are technical subjects, such as engineering, agriculture, and commerce. The fourth is concerned with recreation and physical training; it supervises games, prescribes military drill, and arranges entertainments in which the disabled men are actors as well as spectators. From simple games and light manual tasks the patient is gradually led to some form of effort demanding thought and care. Most of this preliminary work is under the direction of the reconstruction "aides," who are women specially trained for this work. Then in turn come tasks in the ward, followed by others in class-room, shop, or garden. The work is growing. At the present time more than 300 disabled men are taking bedside and ward occupations, and more than 1500 are busy in shops or learning trades. In not a few instances, when finally discharged from the Army, they will be found to have increased their previous earning capacity. The ground work is thus being laid on which to build an efficient economic unit.

SERGENT'S "WHITE LINE" IN SUPRARENAL INSUFFICIENCY.

Dr. E. Sergent was the first to draw attention to the presence of a white line on the skin produced by pressure as an indication of impaired function of the suprarenal capsules. He made this discovery by accident (*Presse Médicale*, Nov. 25th, 1903) while endeavouring to elicit the "red flush" in a case of meningitis, and he interpreted its occurrence as a condition of arterial hypotension with consequent dilatation of the peripheral capillaries, in which a mechanical stimulus to the skin produces local reflex vaso-constriction. The importance of the sign lies in its alleged appearance in suprarenal derangement, even when the melanodermia typical of Addison's disease is not present. The study of the phenomenon has led, in fact, to a recognition of the frequent occurrence of suprarenal insufficiency in various morbid conditions, especially in infective diseases and intoxications. A bronzed skin does not constitute in itself the whole suprarenal pathology; it is neither necessary nor sufficient to establish the diagnosis of a capsular lesion, while asthenia is of primary importance in the symptom-complex of suprarenal insufficiency, and this asthenia is usually associated with hypothermia and arterial hypotension. According to Dr. Sergent, the sign of the white line, when it is present in a characteristic form in the course of an infective malady or acute toxæmia, associated with asthenia and arterial hypotension, indicates changes in the suprarenal cellules; the greater the hypotension the more the line is distinct, broad, and lasting; and it is especially in cases of typhoid fever that these characteristics are most marked. The suggested cause of this sign finds its confirmation in the fact that adrenalin administered to the patient causes the disappearance of the white line, together with the hypotension. Further observations on Dr. Sergent's white line have called forth much criticism as regards its inconstancy or its absence in many cases of suprarenal insufficiency, or its true interpretation. Professor R. Massalongo,[1] of Verona, has done some service in investigating a large number of cases with a view to clearing up these points of difference. He studied the phenomenon of the white line, produced not by

[1] La Riforma Medica, August 24th, 1918.

scratching the skin with the nail, but by rubbing it lightly with the finger tip or some blunt rounded instrument. Out of 400 cases of various diseases he found the white line in an unequivocal form only in 30 cases, and even then often in a transitory and irregular manner; and of these, 22 were cases of typhoid and paratyphoid fever, which constituted 120 of the whole number. His observations led him to the conclusion that diminution of the angiotonic function and cardiotonic power may exist without the presence of the white line and of other symptoms of suprarenal inadequacy, and that arterial hypotension, asthenia, and collapse are not the exclusive function of this inadequacy, since they occur in the course of acute infective diseases independently of it. He found the presence of the line always associated with arterial hypotension and frequently with other symptoms attributable to suprarenal derangement, which, on the other hand, may exist without its presence. Hence by its rarity, inconstancy, and transiency, by its presence or absence in equal proportion in cases where changes in the suprarenal capsules were indisputable, the white line can only be credited with a relative diagnostic importance and significance and cannot be considered as pathognomonic. It has, however, some value from a prognostic point of view, since its maximum frequency is met with in cases of serious import with almost invariably a fatal issue.

HORMONES IN THE CLIMACTERIC.

THE work of Seitz, Wintz, and Fingerhut has led them to believe that ovarial extract is only potent in so far as it contains certain chemical bodies present in the corpus luteum. Two of these have been isolated, luteolipoid and lipamin, both of which have a specific influence on menstruation, the one acting as a hæmostatic, the other encouraging the flow of blood. The firm of "Ciba," in Basle, has put preparations of both of these drugs on the market in tablet form—"sistomensin" containing luteolipoid and "agomensin" containing lipamin. In the *Correspond.-bl. f. Schw. Aerzte* for Oct. 26th Dr. O. Burckhardt-Socin, of Basle, records his experience of sistomensin in five severe cases of climacteric disturbance—flushing, palpitation, sweats—and in two cases of excessive loss at the onset of menstruation in young girls. In each case the symptoms were rapidly relieved, and success in these led the author to try the drug in a case of bleeding fibroid which he would otherwise have sterilised with X rays. Bleeding and pain were both rapidly relieved, and Dr. Burckhardt-Socin recommends a trial of the hormone to his colleagues in similar cases. If further experience should prove the truth of these observations this method of treatment may prove of great value. It is important, however, to remember that there are many authorities who maintain that the internal secretion of the ovary is manufactured not only by the corpus luteum but also by the atretic Graafian follicle cells which have a structure identical with that of the lutein cells. For this reason it would appear probable that preparations made from the whole ovary are more likely to give constant results than those made only from the corpora lutea. As we are quite ignorant whether the secretion of the ovary acts directly on the organism or acts by balancing or influencing the secretion of other internal glands, any conclusions drawn from clinical experience possess many possibilities of error. A further serious drawback hitherto has been our ignorance of the chemical nature of the secretion of the ovary. If the bodies now isolated can be shown to have a fixed composition, and the results obtained are found to be constant, a very definite addition will have been made to our knowledge. It is interesting to note that some gynæcologists are in favour of ovarian extract from which the corpus luteum has been entirely excluded. Indeed, one of the difficulties in admitting the action claimed for the corpus luteum extract lies in determining in what degree of development the corpus luteum is at any given time, as it is impossible to tell by inspection whether a corpus luteum is in process of formation or of involution and disintegration. Many observers, in treating the symptoms of vasomotor disturbance following the removal of the uterus, have been struck by the conflicting results obtained in different cases by the administration of corpus luteum extract, a result which may be explained by the antagonism of the two substances now isolated if one or other happens to be in excess. We hope that other practitioners who have an opportunity of using these preparations will publish their results, so that further light may be thrown upon this interesting method of treatment.

THE OBSERVATION OF THE LIVING NERVE FIBRES OF THE CORNEA.

Dr. J. Strebel, of Lucerne, claims, in a recent number of the *Corresp.-bl. f. Schw. Aerzte* (p. 1442) that he can demonstrate the nerve fibres of the living cornea by means of focal illumination with a Nernst lamp and a corneal microscope. They appear as very fine, silver-grey, opaque, round little bundles in the depth of the corneal parenchyma, at the limbus; they run a wavy course, coming nearer and nearer to the surface as they extend into the cornea, until they end immediately under the conjunctiva. A certain number branch dichotomously at nodes, the branches forming an angle of from 40° to 50°. Occasionally the bundles are surrounded for the first millimetre or two of their corneal course by a sort of sheath-like appearance which is sharply separated from the nerve bundle. Strebel recognises this to be the medullary sheath. He therefore challenges the statement that the nerves always lose their medullary sheath before entering the cornea, and recalls the fact that in some cases the fibres of the optic nerve likewise retain their white sheath after entering the eyeball. The nerves cannot, he says, be mistaken for obliterated vessels by anyone who observes them carefully. Their opaque, silver-grey look, their wavy course, and their dichotomous branching, when it occurs, are all characteristic features. Although this observation dates back to 1913, no notice seems to have been taken of it in this country.

EXTENSIVE OPERATIONS ON THE UPPER LIMB.

IN our present issue Mr. J. W. Geary Grant records three cases in which he performed extensive operations on the upper limb for the removal of malignant disease. In one he performed Berger's operation, or removal of the whole upper limb with the scapula and half the clavicle. In the second case he amputated at the shoulder-joint, and in the third case he removed the scapula. Berger's operation, or interscapulo-thoracic amputation, is a very extensive procedure and the resulting shock is often extreme, though this may be mitigated to some extent by Crile's method of "nerve-blocking." All the modifications of the operation which have been introduced are intended mainly to diminish

the amount of shock. In disarticulation at the shoulder-joint there is much less shock, but the bony surfaces left, notably the prominences of the acromion and the coracoid process, present a very awkward shape. Excision of the scapula is of the greatest value only in cases where the growth is strictly confined to that bone, but in the case recorded by Mr. Grant the glands of the axilla were affected, so that not only at the primary operation but also at two subsequent operations glands were removed from the axilla and from the posterior triangle of the neck. The choice between these various operations is generally dictated by the extent and the limitations of the disease, which clearly show how much must be removed. Though the shock is great with Berger's operation, yet the clean sweep made of the contents of the axilla is in marked contrast to the slow dissection necessary when the axillary glands have to be removed without injury to the vessels and nerves. There is a further point in Mr. Grant's cases worthy of note, and this is that in each case a number of exposures to X rays were given to the affected part, either for the removal of recurrent nodules or for a prophylactic purpose. The benefit of the use of X rays in the prophylaxis of recurrence of malignant disease cannot be considered to be proved, but the method has logical reasoning behind it, and time will show its real value. Mr. Grant is to be congratulated on the results obtained in all of his cases.

GLANDULAR TUBERCULOSIS IN RELATION TO PHTHISIS.

Wallgren[1] has made an inquiry as to the fate of over 500 patients at the surgical clinic of Upsala, Sweden, operated on in the period 1885–1905 for tuberculosis of the lymphatic glands; the inquiry bore special reference to the subsequent occurrence of pulmonary tubercle. He was successful in getting particulars of 224 out of the 500. The number becoming tuberculous was found to be 62—46 from pulmonary phthisis, 9 from miliary tuberculosis, and 7 from tuberculous meningitis. This proportion—over a quarter—is obviously greater than the incidence of pulmonary tubercle in the general population. The disproportion must be discounted a little because 29 of the 224 had signs of tubercle in their lungs while in the clinic. This group showed very heavy after-mortality. But of another group in which the case-notes contained express mention of the lungs being healthy, 11 per cent. became consumptive. The writer concludes that, on the whole, individuals who have had adenitis are more likely than indifferent persons to get consumption, although he does not deny that occasionally, in particular cases, an attack of adenitis may even confer a certain amount of protection against the more serious disease, a species of immunity which has been invoked by Marfan and others. Lastly, those individuals whose adenitis recurred after treatment became consumptive oftener than did the rest. It is a pity that *enquêtes* such as the above are not made oftener, since they have an actuality, an *a posteriori* quality, which is denied to laboratory experiment. So far as the above investigation goes, it confirms the praiseworthy caution of the attitude which refuses to act on the assumption that tuberculosis in early life confers later protection, and builds rather on the obvious facts that infection with tuberculosis having once taken place is extremely likely to recrudesce even after long periods of apparent cure.

[1] Wallgren: Centralblatt für die gesamte Tuberkulose-Forschung, July 31st, 1918.

PUBLIC HEALTH IN EGYPT.

Appointment of Commission.

IN June, 1917, Sir Reginald Wingate, the Egyptian High Commissioner, took the prescient step of appointing a Commission to inquire into the Public Health Department of Egypt, for the present condition of this Department was, in his opinion, capable of improvement, while its future organisation offered problems of a difficult administrative and scientific character.

It was not, however, until June of this year that the preliminary arrangements were completed and the terms of reference settled, when the Commission was duly appointed, as was announced in THE LANCET, with the following composition: President, Lieutenant-Colonel Andrew Balfour, R.A.M.C., Director-in-Chief, Wellcome Bureau of Scientific Research; members, Lieutenant-Colonel G. E. F. Stammers, R.A.M.C.; Mr. E. S. Crispin, Director of the Medical Department of the Sudan Government; and Dr. Charles Todd, Director of Laboratories in the Egyptian Public Health Department.

The terms of reference of the Commission were: (1) To consider the organisation and duties of the Public Health Department and its relations with other departments concerned in public health; (2) to make in general terms suggestions for increasing the efficiency of the Department; (3) to indicate the nature and number of the official appointments to the Department which seem to be required, without nominating persons to fill them. To these ends the Commission was empowered to call the necessary evidence and have access to documents in framing a report to be sent to the Prime Minister or President of the Sultan's Council.

The Commission got to work in a practical manner, determining to make themselves personally intimate with all the existing details and conditions. They instituted a series of inspections in Cairo, Alexandria, and the provinces, thus familiarising themselves with the varying aspects of the work discharged by the Public Health Department. They met on 76 occasions, and the result is the return to the Prime Minister of a very outspoken series of findings.

Report of Commission: Scheme of Central Health Organisation.

The Report begins by recording the impression that the general plan devised by the Public Health Department for dealing with the many and difficult health problems of Egypt was a sound one. It had been valuable in checking the spread of cholera, plague, typhus, and relapsing fever; it had none of the haphazard character with which it is generally credited; and for future needs its scheme is well fitted both for adaptation and development. The Commission finds, in fact, that the future needs of the country from the health point of view have also received great attention, while they single out for special and favourable mention the last Assistant-Director of the Department, Dr. Cyril Goodman. But the Report states that the Department suffers from having no proper official status; being not an entity but a branch of the Ministry of the Interior, it has no direct official access to the High Commissioner, while the channels—namely, the Adviser or the Under-Secretary of State for the Interior—are without the necessary technical training to understand the needs of the Public Health Department. Upon the outbreak of war the efficiency of the Public Health Department, already hampered by the multifarious nature of its duties, was gravely affected, says the Report, by the fact that its officials were allowed to be seconded for duty with the troops at the very moment when the personnel of the Department should have been strengthened instead of weakened, although effective organisation managed to avert any disaster. With general reference to the present-day conditions in Egypt so far as they have a bearing on public health, the report is sanguine. Developments in roads, railways, and canals will occur, having regard to the successful issue of the war, while education in modifying the outlook of the Egyptian peasant and rendering the future of sanitation more hopeful is expected to have a powerful effect. "It is obvious," says the Report, "that the signs are propitious, and though, owing to the war, the time may not yet be actually ripe for extensive modifications in health organisation, yet it is clear that the present period of change and advance offers special facilities for the consideration of a scheme of reform." But immediately afterwards the Report speaks in

almost unmeasured language of the plague of filth in Egypt, and the first section concludes by unanimous agreement that a Ministry of Health is essential for securing proper sanitary reform in the Protectorate.

A scheme for a central health organisation is then outlined. It commences with the statement that the Ministry of Health must be a separate bureau with an Under-Secretary of State at its head as President. Immediately below him it is suggested there should be a Director-General of Health, who is intended to be the main driving force in the Ministry, as his duties will require him to coördinate the work of important subordinates as well as to prepare the annual Budget. The President will also have the advantages of a Technical Adviser, who, under the alternative title of Director of Medical Intelligence, will conduct a bureau of information, control the laboratories and research work, keep in touch with scientific developments in other countries, and be responsible for an educational museum. The Central Board of Health, it is suggested, will be completed by seven officers appointed as directors respectively of Sanitary, Epidemic, and Medical Services, of Lunacy, Medical Education, Public Health Laboratories, and Sanitary Engineering. The first three of these Directors being designated as *ex-officio* members of the Board, it would seem that it is intended to co-opt the others as occasion requires. A Secretary-General is added not only to manage the records and deal with all questions relating to subordinate personnel but also to sift the work of the Director-General, who might otherwise become overburdened with detail. The Report goes very carefully into the separate and combined duties of these various important central officials, indicating that technical inspection will undoubtedly be needed in many directions, as for provincial and ophthalmic hospitals and pharmacies, schools, and food and water control. The establishment of a chair of Hygiene in the Kasr-el-Aini School of Medicine and of a Diploma in Public Health is strongly advocated. The Report then passes to the consideration of the provincial organisation of public health in Egypt.

Provincial Administration.

The Report becomes very detailed in character when dealing with provincial organisation for the public health of Egypt, for here, rather than in central administration, are the chief defaults to be found, and here reform will get its quickest returns. The first weakness noted in provincial administration is the paucity of British Provincial Inspectors. These officers are few in number, do not live permanently in their districts, and are kept so constantly moving about by the multifarious nature of their duties that they rarely get into close touch with any section of the population. "A good type of man," says the Report, "has undoubtedly been an officer of the Royal Army Medical Corps, possibly in part because he has received a special training in hygiene and understands discipline. This source of supply should be readily available in the future." Reference here must clearly be made to medical men who have received temporary commissions in the Royal Army Medical Corps during the past four years, because there could not possibly have been any successful demand made previous to the war upon the Royal Army Medical Corps, whose cadre was then lamentably short. The Report continues: "The posts should be filled by men of about 25 years of age, and they should preferably have held some hospital appointment before joining the service of the Ministry. It would be a distinct advantage if they possessed diplomas in public health or in tropical medicine and hygiene." Such men will not be found in any quantity relinquishing at the age of 25 the Royal Army Medical Corps, but it seems possible, if the Egyptian bureau of health comes into rapid being, that British Provincial Inspectors might be obtained from among those who have held temporary commissions. The sort of work indicated should be quite attractive to many after their military experiences, but if Egypt is to get any large supply the conditions of service must be inviting.

The Report indicates that these Divisional Inspectors, as they are officially called, should be first placed under a senior officer so as to become familiar with Egyptian manners and to acquire Arabic, while arrangements, it is proposed, should be made whereby they can visit Cairo in rota and get an insight into the higher machinery of the service. The general duties of a Divisional Inspector may be described as those of a medical officer of health of the *Mudiria* (province or county). The Report recommends not only that there should be many more Divisional Inspectors, but that they should be better paid and that there should be a chance for Health Inspectors in the Mudiria (who are Egyptian doctors and next in rank to Divisional Inspectors) being raised to the position. Below the Mudiria Health Inspectors comes the *Markaz* doctor, on whom at the present moment, and for very low pay, there fall the private practices in the Markaz as well as much public health work, care of schools and prisons, registration duties, and medico legal work. A Markaz, it may be said, is a district of a province, and may contain many large villages. Some of the Markazes have, we understand, as many as 80,000 inhabitants. The Commission responsible for the Report have perhaps devoted more time and thought to the remedy of the Markaz conditions than to any other part of their work. They obtained valuable evidence and arrived at the conclusion that the best course to pursue eventually would be to divide the Markaz doctors into two categories according to their work, (*a*) Sanitary and (*b*) Medical. The (*a*) Markaz doctor would under the scheme be in sanitary charge of public works, excluded from private practice, and be responsible for general sanitation, notification and public treatment of communicable disease, vaccination, quarantine, and care of pilgrims. The (*b*) Markaz doctor would be in charge of the medical side of some of this work—namely, the treatment of communicable disease, the medical work done in prisons and schools, the examination of prostitutes, and all medico-legal work. He would be, of course, allowed private practice, which would, as stated, be denied to the (*a*) Markaz doctor, to whom, however, promotion to the Mudiria Health Inspectorships would be open. The Commissioners recognise that at the present time this scheme is not feasible, but suggest that it be given a trial in certain suitable areas. To meet immediate needs they propose a large increase in the number of Markaz doctors, whose duties would thus be lightened in some measure. A notable recommendation in the Report is the introduction of qualified British sanitary inspectors—i.e., men of the N.C.O. class—both in the case of the provinces and the large towns. In the former they would be attached directly to the British Divisional Inspectors and would supervise the work of the Egyptian inspectors of nuisances, who at present do not exist in the provinces, and whose creation is strongly urged.

Provision is made in the Report for the institution of training centres in the large towns, where the methods and appliances of sanitation can be taught to these inspectors of nuisances. An eloquent plea is here founded on Lord Kitchener's latest work for village sanitation service. The authors of the Report protest against allowing the fellaheen to live under existing sanitary conditions. Proper village water-supplies, incinerators, latrines, and conservancy systems are required to make Egyptian village life less of a sanitary scandal.

Concluding Remarks.

The various departments of medical service receive detailed notice—the department of epidemic service, of hospital management and inspection, of police, prison, and railway medical service, of school inspection and other subdivisions of medical work are all carefully noticed in the Report, as well as such subjects as medical schools and research laboratories, public health laboratories, and vaccination institutions. A special section of the Report is devoted to the public health of Alexandria, Cairo, and other large towns. We hope that the Report will soon be printed and available for the study of the profession. It is an outspoken document, covering a large amount of ground and giving information in a readable and intelligible form, which is valuable to all sanitarians as well as to those whose interests lie specially in Egypt. We trust, therefore, that the Report will not share the ill-fortune of many of its similars and remain the mere literary record of an ideal. It can easily be understood that the unification of health activities in such a country as Egypt constitutes a grave problem, but it is exactly the sort of problem which the British mind is best fitted to tackle. If those in authority are prompt in translating the recommendations of this Report into the legislation of the Protectorate their reward, in the future saving of trouble, will be very great.

Miss Gladys K. M. Simmons, who died of pulmonary tuberculosis at Bournemouth on Nov. 15th on the eve of her 27th birthday, had for the last two years been a valued helper in the editorial work of THE LANCET, although confined to her bed.

A MEMORANDUM ON INFLUENZA
FROM THE MEDICAL RESEARCH COMMITTEE.

THE secretary of the Medical Research Committee has sent us for publication the following summary of recent work done in foreign countries on the epidemiology and bacteriology of influenza.

Etiology and Clinical Course.

At a meeting of the Greifswald Medical Society on July 18th, Friedberger[1] stated that the term "grippe" was of French origin, being derived either from "gripper," to "seize," or from an insect called "grippe" which was regarded as the cause of the disease in the middle of the eighteenth century. The name "influenza" originated from the expression *ab occulta coeli influentia* used by the Greifswald physician, Calenus, in 1597. In a note on the history of influenza in Schleswig-Holstein, Hanssen,[2] of Kiel, states that he has found records of a "Spanish sickness" in 1566, 1580, and 1592, when the disease spread very rapidly and claimed many victims.

Orticoni, Barbie, and Leclerc,[3] in a note on the microbial flora of influenza, state that in addition to the usual micro-organisms of acute respiratory affections, such as pneumococci, streptococci, and pneumobacilli, they were able to isolate Pfeiffer's bacilli from the blood and pleural fluid from a certain number of influenza patients. It was chiefly towards the end of the disease and in the severest cases that Pfeiffer's bacilli were found, and almost always in association with other micro-organisms. Further investigations are needed to determine whether Pfeiffer's bacillus plays the principal rôle or is only of secondary importance in the etiology of influenza.

Florand[4] records cases tending to show that the present epidemic, which at first was so mild, is assuming a much graver character, especially as regards its pulmonary, broncho-pulmonary, pleural, and cardiac manifestations. The mild nature of the early cases in contrast with the severity of the later ones is also emphasised by Morelli (*vide infra*). Lampe[5] states that while the disease in the majority of cases observed in the Dresden Municipal Hospital ran a rapid and favourable course, 34 per cent. were complicated by severe diseases of the lungs and pleura. The frequency of cardiac dilatation and neurasthenia as sequelæ of influenza is noted by Espina.[6]

The Disease in Italy.

The high incidence of the disease in the Italian Army is shown by the fact that in some divisions the sick-rate was 90 per cent., and in one field hospital 40 per cent. of the staff went sick (Pavesi[7]).

Morelli,[8] in charge of a military hospital at Forli, states that the disease first appeared towards the end of April, and progressively increased in frequency until it reached its height in the last week of May and the first week of June, and then declined until it had almost disappeared in July. The first attacks were so mild that the men were able to keep on duty, but the subsequent cases were obliged to take to bed owing to the severity of the symptoms. Morelli distinguishes three groups of cases: 1. Very mild, ambulatory, almost abortive attacks, the symptoms consisting almost exclusively of an exanthem, enanthem, and slight general symptoms, such as headache, malaise, and a subfebrile temperature. 2. The ordinary type. 3. Severe cases with localisation of the infection chiefly in the respiratory tract. Gastro-intestinal symptoms were never prominent, but involvement of the nervous system was shown by headache, convulsions, and fainting, and in two cases by nuchal rigidity and Kernig's sign. The most characteristic feature of the disease was an exanthem which was present in almost all the cases at an early stage. It was polymorphous in character, sometimes assuming a diffuse erythematous form, varying from a bright red to a pale pink, localised on the face, trunk, and upper limbs, but hardly ever on the hands and rarely on the lower limbs. In some cases it closely resembled measles but was not followed by desquamation. In other cases it assumed the form of urticaria or erythema nodosum or affected the distribution of a prodromal rash of small-pox in the axillæ, hypochondria, and groins. An enanthem was present in all cases and consisted of an erythema involving the soft palate, uvula, and pillars of the fauces.

Influenza in Switzerland and Spain.

In a letter from Zurich, published on Sept. 8th, Häberlin[9] states that the Swiss Army has suffered severely from the influenza epidemic, not only the troops at the frontier being affected, in whose case defective hygiene might be held responsible, but also mobilised divisions in the country, where accommodation was good, and even recruits in barracks. Only isolated cases occurred in June, but towards the middle of July the epidemic broke out with great violence, so that 50 per cent. and more of the men contracted the disease in a few days. Many severe and fatal cases were observed both in the Army and in the civil population. Young persons were much more frequently attacked than the older generation, which had gained immunity from the 1889–90 epidemic. In not a few cases the infection ran a fulminating course, proving fatal in one or two days with all the signs of septicæmia. Many cases which at first seemed mild suddenly developed broncho-pneumonia just after convalescence had set in. In some troops three-quarters of the effectives fell sick. The number of fatal cases in the Army was about 500. Medical men formed a relatively high percentage of the victims, especially young doctors attached to hospitals or in the Army. Berne suffered most from the epidemic and the various places in the Bernese Jura, as well as some internment camps, such as the Chateau d'Oex.

On a discussion on the prevailing epidemic held at the Spanish Royal Academy of Medicine, Sanz[10] stated that among 120 cases under his care, 17 were of a hypothermic form, the characteristic features of which were not only the absence of fever but the persistence of a subnormal temperature, a scarcity of respiratory symptoms which were usually confined to the upper respiratory tract, intense pain in the fauces, aphonia, and a paroxysmal cough accompanied by spasm of the glottis. Intestinal disturbance was occasionally present at the onset. He had observed three varieties of nervous complications in this epidemic:—

1. Meningeal. In two cases in which lumbar puncture was performed the tension of the cerebro-spinal fluid was four times higher than the normal.

2. Neuralgic syndrome, chiefly assuming the form of sciatica or trigeminus neuralgia. In all the cases the neuralgia appeared at the onset of the disease and lasted throughout the febrile period.

3. Psychical syndrome, such as mental confusion and melancholia.

Description of a Sign.—Influenza Spondylitis.—Effect on Kidneys.

In a paper on a typical tender spot in influenza, Boeckler[11] draws attention to a sign which, in his experience, is never absent in true influenza, and the absence of which excludes the disease. This tender spot, which is usually bilateral, but may be present on one side only, is found as follows. A horizontal line is drawn two finger-breadths above the highest points of the iliac crests, with the patient in the vertical position. The point where this horizontal line intersects the outer border of the longissimus dorsi is the characteristic influenza tender point, which corresponds, according to Boeckel, to the space between the third and fourth lumbar vertebræ. This sign is often the only objective finding present at the beginning of the disease, and sometimes persists after all the other symptoms have disappeared. Boeckel has never found it present in any other disease, and considers that its constant presence in influenza proves that a more or less marked neuritis is constant in this disease, affecting all the branches of lumbar segment, and the fourth most of all. This hypothesis accounts for the pain in the back and legs and also for the giving way of the knees so frequently observed in influenza, as the fourth lumbar nerve sends motor fibres to the inner side of the leg.

A case of influenza spondylitis resembling typhoid spine and giving rise to lordosis is reported by Bregman.[12] X rays

showed considerable widening of the lumbar intervertebral spaces, but no important changes in the bodies of the vertebræ. Recovery took place in three months under treatment by salicyl preparations and electric-light baths.

According to the official report quoted by Knack [13] on the epidemic of influenza in the German Army in 1889–90, among 55,263 cases there were only 10 instances of serious renal disease which did not differ in any respect from that occurring after other infectious diseases. Subsequent experience has confirmed that of the 1889 epidemic, and recent text-books state that post-influenzal nephritis is uncommon. During the present epidemic Knack has found a trace or cloud of albumin almost invariably present in mild and moderate cases of uncomplicated influenza. The albuminuria usually appeared during the first few days of the disease, and disappeared with, or shortly after, the fall of the temperature, but in rare cases it persisted for several weeks. From examination of the urinary sediment Knack has occasionally found focal and diffuse glomerulo-nephritis, and in rare cases nephrotic and purulent renal changes. An outbreak of influenza in the department for war nephritis gave Knack an opportunity of studying the effect of influenza on pre-existing renal disease. In many cases the kidney did not show any reaction, and in others there was a more or less pronounced but transitory exacerbation of the renal condition.

THE MEDICAL RESEARCH COMMITTEE:

COMMITTEES FOR SPECIAL PURPOSES.

IN the fourth annual report, just issued, of the Medical Research Committee (Cd. 8981. Price 4*d.*) an appendix is devoted to the constitution and personnel of the various committees for special purposes which have arisen during the war. We reproduce this appendix for the benefit of our readers.

(1) *The Incidence of Phthisis in Relation to Occupations.*

To investigate and report upon the incidence of phthisis in relation to particular occupations, and to prepare and suggest schemes for special research work in connexion therewith.

Dr. Addison (chairman); Dr. John Brownlee; Professor William Bulloch, F.R.S.; Dr. E. L. Collis; Dr. Major Greenwood; Dr. Leonard Hill, F.R.S.; Dr. Benjamin Moore, F.R.S.; with Sir Walter M. Fletcher, F.R.S. (secretary to the Medical Research Committee).

(2) *Surgical Shock and Allied Conditions.*

To undertake the coördination of inquiries into surgical shock and allied conditions, with a view to the better correlation of laboratory and clinical observations.

Professor W. M. Bayliss, F.R.S. (chairman); Professor F. A. Bainbridge; Professor W. B. Cannon (Harvard); Colonel T. R. Elliott, F.R.S.; Dr. John Fraser; Colonel H. M. W. Gray; Dr. P. P. Laidlaw; Professor A. N. Richards, Ph.D. (Pennsylvania); Professor C. S. Sherrington, F.R.S.; Professor E. H. Starling, F.R.S.; Major-General Cuthbert Wallace; Dr. H. H. Dale, F.R.S. (secretary). (With corresponding members in France, Italy, and America.)

(3) *Standardisation of Pathological Methods.*

To consider how far it may be practicable and desirable to obtain standardisation of routine pathological methods, and to report upon this. The Committee are empowered to coöpt additional members for particular divisions of their subject.

Professor J. G. Adami, F.R.S. (chairman); Professor F. W. Andrewes, F.R.S.; Professor W. Bulloch; Captain S. R. Douglas (secretary). Additional members for particular divisions of the subject: Colonel L. W. Harrison; Dr. C. H. Browning; Dr. J. W. H. Eyre.

(4) *Salvarsan.*

To consider the methods of manufacture, biological testing, and clinical administration of salvarsan and its substitutes used in this country, and the results of these, and to propose specific investigations aimed at improving those methods and results.

Sir Humphry D. Rolleston (chairman); Professor F. W. Andrewes; Professor William Bulloch; Dr. F. J. H. Coutts (secretary); Dr. H. H. Dale; Colonel L. W. Harrison; Surgeon Commander D. W. Hewitt, R.N.

(5) *Chemical Warfare Medical Investigations.*

Appointed by the Director-General, Army Medical Service, with the concurrence of the Controller of Chemical Warfare, to prepare reports, based upon information received from all sources at the Chemical Warfare Department, for submission to him with a view to their distribution to those concerned, to make suggestions for further co-ordinated medical investigations that may seem desirable, and to advise him generally in respect of the scientific medical aspects of chemical warfare.

Professor A. R. Cushny, F.R.S. (chairman); Mr. J. Barcroft, F.R.S.; Professor W. M. Bayliss; Professor A. E. Boycott, F.R.S.; Dr. H. H. Dale; Dr. J. S. Edkins (secretary); Sir Walter M. Fletcher; Dr. J. S. Haldane, F.R.S.; Dr. Leonard Hill; Lieutenant-Colonel J. C. Meakins, C.A.M.C.; Major H. S. Raper, R.A.M.C.; Dr. Frank Shufflebotham; Colonel A. B. Soltau. (With corresponding members in France, Italy, and England.)

[13] Knack, A. V.: Med. Klin., Berl. u. Wien, 1918, xiv., 902–4.

(6) *Anaerobic Bacteria and Infections.*

With a view to the better coördination of inquiries into the characters of anaerobic organisms, with special reference to the bacteriology of anaerobic wound infections, the Medical Research Committee invited the following to serve as a Special Investigation Committee for this purpose.

Professor William Bulloch (chairman); Dr. W. E. Bullock; Captain S. R. Douglas; Dr. Herbert Henry; Dr. James McIntosh; Dr. R. A. O'Brien; Miss Muriel Robertson, M.A. (secretary); Dr. C. G. L. Wolf. (With corresponding members in France.)

(7) *Accessory Food Factors ("Vitamines").*

Appointed by the Medical Research Committee jointly with the Lister Institute of Preventive Medicine to consider and advise upon the best means for advancing and coördinating the various lines of inquiry into the modes of action of the factors in metabolism which are independent of the provision of energy.

Professor F. Gowland Hopkins, F.R.S. (chairman); Miss Harriette Chick, D.Sc. (secretary); Dr. J. C. Drummond; Professor Arthur Harden, F.R.S.; Dr. E. Mellanby. (With corresponding members with the Forces in the East and in America.)

(8) *Air Medical Investigation.*

The Medical Administrative Committee of the Air Ministry in consultation with the Medical Research Committee, and with the concurrence of the Air Council, appointed the following Committee:—(*a*) To prepare reports for submission to them with a view to their distribution to those concerned. (*b*) To make suggestions for further coördinated medical investigations that may seem desirable. (*c*) To advise them generally in respect of the scientific medical aspects of aeronautics.

Dr. Henry Head, F.R.S. (chairman); Sir Walter M. Fletcher; Dr. M. Greenwood; Dr. Leonard Hill; Dr. W. H. R. Rivers, F.R.S.; Professor C. S. Sherrington; Professor C. E. Spearman, Ph.D.; Colonel Martin Flack, R.A.F. (secretary); the Secretary, Medical Administrative Committee (ex-officio). Corresponding members in France: Major J. L. Birley; Captain C. H. D. Corbett; Lieutenant-Colonel G. Dreyer; Mr. Sydney Scott.

(9) *Dysentery.*

In May, 1918, the following Committee was appointed by the Director-General, A.M.S., for the purpose of investigating problems in connexion with the incidence and segregation of cases of amœbic and bacillary dysentery, more especially with relation to the disposal of carriers, and such other problems as may be placed before it.

Sir William Leishman, F.R.S. (chairman); Professor F. W. Andrewes; Dr. G. S. Buchanan; Mr. Clifford Dobell, F.R.S.; Sir Walter M. Fletcher; Dr. G. T. Western (secretary).

(10) *Industrial Fatigue Research Board.*

Appointed in June, 1918, by the Department of Scientific and Industrial Research jointly with the Medical Research Committee to consider and investigate the relations of the hours of labour and of other conditions of employment, including methods of work, to the production of fatigue, having regard both to industrial efficiency and to the preservation of health among the workers.

Professor C. S. Sherrington (chairman); Dr. E. L. Collis; Sir Walter M. Fletcher; Mr. W. L. Hichens; Mr. Edward Hopkinson, D.Sc.; Dr. M. T. Legge; Mr. D. R. Wilson (secretary). (The appointments to the Board are not yet completed.)

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

A MEETING of the Executive Committee of the Fund was held at the offices of THE LANCET on Nov. 18th, when the position of the Fund was considered, having regard to the gradual reclamation of Belgium from the German occupation.

Sir RICKMAN GODLEE, the Chairman of the Committee, said that after inquiry he found that no definite announcement could yet be made as to when prompt intercommunication between the Committee of the Fund and the Comité Mixte sitting in Brussels could be made. The feeling of the Committee was that, with regard to the money remaining in their hands, as well as future subscriptions, some direct communication with the Belgian body would now be useful. It was decided that steps should be taken to obtain through the Commission for Relief in Belgium a statement from the Comité Mixte, representing the medical and pharmaceutical professions in Belgium, as to the present position. The Committee noted with pleasure that the subscriptions to the Second Appeal of the Fund were still coming in, the North of England Branch of the British Medical Association, through Dr. J. Don, the honorary secretary of the Branch, having been notably generous. Relying on two things—namely, the subsidy until the end of the year of £200 a month from the American Red Cross, and the recurring generosity of the medical profession—it was decided to resume the mensuality of £800 per month.

The Committee formally expressed deep regret at the death of Mr. Meredith Townsend, who had been an active and assiduous member of their body, and through whose instrumentality a varied and valuable assortment of medical instruments had been distributed from the Apothecaries'

Hall, London, to Belgian doctors, both in this country and fighting with the Belgian Army.

SUBSCRIPTIONS TO THE SECOND APPEAL.

The following subscriptions have been received up to Monday last, Nov. 18th:—

	£	s.	d.
North of England Branch B.M.A. (per Dr. J. Don, Hon. Sec.)—			
Dr. James Hudson ...	5	5	0
Dr. J. Wishart	1	1	0
Dr. J. H. R. Garson ...	1	1	0
Dr. J. McDonald ...	2	2	0
Dr. T. G Ainsley ...	5	5	0
Dr. C. Busan	1	1	0
Dr. F. Horseman ...	1	0	0
Dr. James Don... ...	5	5	0
Dr. A. Livingston ...	5	5	0
Dr. A. C. Burnell ...	5	5	0
Dr. Alfred Cox (monthly)	1	1	0
Dr. J. Herbert Sanders (per Sir Rickman Godlee)	1	10	10
Dr. R. H. Western... ...	20	0	0
H. L.	5	0	0
Sydenham District Medical Society (per Dr. F. G. Swayne)	7	7	0

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

URBAN VITAL STATISTICS.

(Week ended Nov. 16th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had increased from 11·4 to 43·8 per 1000 in the seven preceding weeks, declined to 33·7 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 44·0 or 11·5 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 14·8 in Bournemouth, 14·9 in Southampton and in Wallasey, and 15·0 in Portsmouth, to 62·0 in Oldham, 68·4 in Coventry, 68·7 in Nottingham, 70·2 in Norwich, and 84·6 in Rotherham. The principal epidemic diseases caused 186 deaths, which corresponded to an annual rate of 0·6 per 1000, and included 61 from infantile diarrhœa, 53 from diphtheria, 31 from whooping-cough, 26 from measles, 9 from scarlet fever, and 6 from enteric fever. The deaths from influenza numbered 5916, or 1644 below those recorded in the previous week, and included 1665 in London, 246 in Birmingham, 241 in Sheffield, 235 in Manchester, 208 in Leeds, 198 in Nottingham, and 161 in West Ham. The 1171 cases of scarlet fever and 1086 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 27 and 69 below the respective numbers remaining at the end of the previous week. The causes of 74 deaths were uncertified, of which 10 were registered in Nottingham, 6 each in Birmingham and South Shields, and 5 each in London, Liverpool, and Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 23·9, against 30·5 and 27·0 per 1000 in the two preceding weeks. Of the 1103 deaths from all causes, 48 were classified to influenza, which was also stated as a contributory cause in 331 deaths classified to other diseases; in the previous week these numbers were 87 and 447 respectively. The 404 deaths in Glasgow corresponded to an annual rate of 18·9 per 1000, and included 5 from diphtheria, 3 from whooping-cough, 2 from infantile diarrhœa, and 1 from scarlet fever. The 234 deaths in Edinburgh were equal to a rate of 35·6 per 1000, and included 4 from whooping-cough, 2 each from diphtheria and infantile diarrhœa, and 1 from scarlet fever.

Irish Towns.—The 349 deaths in Dublin corresponded to an annual rate of 45·6, or 14·4 per 1000 below that recorded in the previous week, and included 141 from influenza, 4 from infantile diarrhœa, 3 from diphtheria, 2 from scarlet fever, and 1 each from enteric fever and measles. The 412 deaths in Belfast were equal to a rate of 54·7 per 1000, and included 3 from infantile diarrhœa and 1 each from scarlet fever and diphtheria.

LITERARY INTELLIGENCE.—A work on "Dr. John Fothergill and His Friends," by Dr. R. Hingston Fox, will shortly be issued by Messrs. Macmillan. It will give a picture of the Quaker physician, and his influence on the advance of therapeutics in the eighteenth century. The book will deal with Fothergill's large contributions to botany, his work in education and politics, and especially his relations with the American provinces. Portraits of Fothergill, Dimsdale, Lettsom, Franklin, and others are included.

COAL FOR INVALIDS.—It has been reported to the Coal Controller that local fuel overseers are receiving very many medical certificates authorising additional coal rations to householders on account of illness in the family. Many of these medical certificates have been given, in the opinion of the Coal Controller, without the necessary consideration of the serious coal shortage, and with this view he is drawing the attention of medical men to the necessity of granting these certificates only in cases of real hardship. The only condition under which a medical certificate for an extra coal ration on account of illness should be given is, says the Coal Controller, where the patient is to remain in bed and where a fire in the bedroom is necessary for recovery; and he states that "one cwt. to one and a half cwt. a week can be allowed for bedroom fires in these circumstances and only for the time the patient remains in bed." The notice to medical men is accompanied by an unfortunately worded threat of ignoring medical certificates unless the real hardship of the case is clear to his department.

The War and After.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue:—

Died of Wounds.

Capt. J. Gaston, M.C., R.A.M.C., attached Suffolk Regiment, qualified at Belfast in 1906, and prior to joining the R.A.M.C. was in practice at Cloughmills, co. Antrim. The award of the Military Cross was recorded in THE LANCET of August 4th, 1917, p. 175.

Lieut. P. R. Shannon, R.A.M.C., came over as a member of the Canadian Expeditionary Force, and later was attached to the R.A.M.C.

Died.

Capt. R. S. Cocke, R.A.M.C., was a student at King's College Hospital, London, and qualified in 1900. He held appointments at the Cambridge Hospital, Aldershot, at King's College Hospital, and at St. Pancras Infirmary. Prior to joining the R.A.M.C. he was in practice in Wimpole-street, and was on the staff of the Royal Ear Hospital, Soho, and of King's College Hospital. He died in London of disease, contracted whilst on active service in the East.

Capt. L. A. Winter, R.A.M.C., was a student at St. Bartholomew's Hospital, London, and qualified in 1892. He held appointments at the East London Hospital for Children, at the Kent and Canterbury Hospital, and at St. Bartholomew's Hospital. Prior to joining the R.A.M.C. he was in practice at Sheerness, where he was medical officer to the Post Office, divisional surgeon to the St. John Ambulance Brigade, acting commandant and medical officer to the local V.A.D., and civil surgeon to the Well Marsh Military Hospital, Sheerness. He died in France of pneumonia.

Capt. H. G. F. Spurrell, R.A.M.C., was educated at Oxford and at the London Hospital, and qualified in 1907. During 1916–17 he was temporary medical officer at Obuasi, South Ashanti, and later joined the R.A.M.C. He died at Alexandria of pneumonia.

Col. S. C. Philson, A.D.M.S., R.A.M.C., was a student at King's College Hospital, London, and qualified in 1883. He joined the R.A.M.C. shortly afterwards.

Capt. A. M. Jukes, I.M.S., was a student at St. Bartholomew's Hospital, London, and qualified in 1906. Prior to joining the I.M.S., in which at the time of his death he was Deputy Sanitary Commissioner of the Presidency Circle, Bengal, he held appointments at Shillong, Assam, and at the Royal Infirmary, Hull. He died in Egypt of neuritis and heart failure following rheumatic fever.

Lieut. J. Dow, I.M.S., qualified at Aberdeen in 1914, and after holding an appointment at the Aberdeen Royal Infirmary he joined the R.A.M.C., and later transferred to the I.M.S.

Capt. J. M. Downie, R.A.M.C., was educated at Cambridge and at Glasgow Universities, and qualified in 1916. After holding an appointment at the Western Infirmary, Glasgow, he joined the R.A.M.C.

Lieut.-Col. J. E. Hodgson, R.A.M.C., was a student at Owens College, Manchester, and qualified in 1898. He held an appointment at Barnes Convalescent Hospital, Cheadle, and joined the R.A.M.C. in 1899. He died at Salonika of pneumonia following influenza.

Capt. C. D. Hamilton, Canadian A.M.C., qualified at McGill University, Montreal, in 1911, and prior to joining the Canadian Contingent was in practice in Cornwall, Ontario, Canada.

Lieut. W. McL. McLeod, Canadian A.M.C.

Lieut. R. H. Lalande, Canadian A.M.C.

Wounded.

Capt. A. Hunter, R.A.M.C., attached Royal Engineers.
Capt. A. U. Millar, R.A.M.C.
Capt. P. G. Leeman, R.A.M.C.
Capt. J. Manuel, M.C., R.A.M.C.
Major W. H. Morrison, R.A.M.C.
Capt. C. H. G. Prance, R.A.M.C.
Capt. I. W. Jones, R.A.M.C., attached Indian Army.
Capt. R. Rodger, R.A.M.C., attached Indian Army.
Major D. H. Russell, M.C., R.A.M.C., att. Northumberland Fusiliers.
apt. C. N. Coad, M.C., R.A.M.C.
Capt. J. Pryce Davies, R.A.M.C., attached R.F.A.
Capt. J. Scott, R.A.M.C., attached Manchester Regiment.
Major H. J. D. Smythe, R.A.M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Lieut. J. E. C. MacVicker, R.A.F., reported missing, now believed to have been killed, eldest son of Dr. C. G. MacVicker, J.P., of Street, Somerset.

Capt. E. V. Morse, M.C., The Buffs, killed in action, second son of Mr. T. H. Morse, F.R.C.S., of Deal.

Lieut. J. Webster, M.C., R.A.F., killed in action, only son of Dr. J. A. Webster, late of Launceston and Sorell, Tasmania.

Capt. J. C. Woollett, R.A.F., died of pneumonia, son of Dr. C. J. Woollett, of Streatham, London, S.W.

Second Lieut. J. W. B. Rowland, R.F.A., killed in action, only son of Dr. E. D. Rowland, I.S.O., British West Indies Medical Service.

Col. S. C. Philson, A.D.M.S., R.A.M.C., died of pneumonia at Karachi, India, son of the late Dr. W. Philson, of Cheltenham.

Capt. A. M. Jukes, I.M.S., died of heart failure after rheumatic fever, only son of Dr. A. Jukes, of the Church Missionary Society.

Lieut. E. L. Prichard-Evans, R.A., died at King's Lynn of pneumonia, youngest son of the late Dr. E. Prichard-Evans, of Mountain Ash, Glam.

Capt. H. S. Lyle, M.C., Canadian Mounted Rifles, killed in action, third son of the late Dr. R. C. Lyle, of Dunmow, Essex.

Gunner C. G. Kelly, R.F.A., killed in action, son of the late Dr. B. Kelly, of Rotherhithe, London, S.E.

Driver W. Marshall, R.H.A., died abroad of influenza, son of Dr. J. Marshall, of Wickford, Essex.

THE HONOURS LIST.

The following appointments of medical officers to the Order of the British Empire are announced:—

Officers: Capt. D. H. Fraser, M.C., R.A.M.C. (for an act of gallantry not in the presence of the enemy); Temp. Capt. D. F. Borrie, R.A.M.C.; Maj. S. R. Christophers, C.I.E., I.M.S.; Capt. W. Dunlop, R.A.M.C. (Spec. Res.); Temp. Capt. E. N. Glover, R.A.M.C.; Maj. F. P. Mackie, I.M.S.; Temp. Lieut.-Col. D. Macauley, R.A.M.C.; Capt. (acting Maj.) W. D. Miller, South African M.C.; Lieut.-Col. E. R. Rost, I.M.S.; Maj. E. L. Scott, M.C., I.M.S.; Maj. C. E. Southon, I.M.S.; Capt. R. Bury, Nyasaland M.S.; Temp. Capt. G. D. H. Carpenter, Uganda M.S.; Capt. W. H. Elliott, R.A.M.C. (Spec. Res.); Capt. G. B. Fleming, R.A.M.C. (T.F.); Capt. W. H. Kauntz, East African M.S.; Temp. Capt. D. McIntyre, R.A.M.C.; Maj. E. Gibbon, R.A.M.C.; Mr. A. H. Spurrier, C.M.G., L.R.C.P., attached Sanitary Service, East African Force.

FOREIGN DECORATIONS.

French.

Légion d'Honneur: Croix de Chevalier.—Lt.-Col. J. H. Hugo, D.S.O., I.M.S.

Croix de Guerre.—Maj. C. E. W. S. Fawcett, R.A.M.C.; Lt.-Col. P. G. Brown, Canadian A.M.C.; Lt.-Col. R. D. Campbell, D.S.O., Australian A.M.C.; Maj. (Temp. Lt.-Col.) R. T. Collins, D.S.O., R.A.M.C.; Capt. W. P. Croker, R.A.M.C.; Capt. (Acting Maj.) J. Dale, R.A.M.C.; Temp. Capt. J. L. Jackson, R.A.M.C.; Lt.-Col. A. B. Lyon, R.A.M.C.; Lt.-Col. A. H. Marks, D.S.O., Australian A.M.C.; Capt. (Acting Maj.) G. S. Parkinson, D.S.O., R.A.M.C.; Capt. (Temp. Col.) S. M. Smith, C.B., R.A.M.C. and A.M.S.; Lt.-Col. (Temp. Col.) A. B. Soltau, C.M.G., R.A.M.C. and A.M.S.; Maj. (Temp. Lt.-Col.) V. O Stacy, Australian A.M.C.; Maj. (Acting Lt.-Col.) C. G. Thomson, D.S.O., R.A.M.C.; Lt.-Col. J. Tobin, R.A.M.C.; Capt. (Acting Lt.-Col.) T. B. Wolstenholme, R.A.M.C.; Capt. W. L. R. Wood, M.C., R.A.M.C.; Col. R. J. Blackham, C.M.G., C.I.E., D.S.O., A.M.S.; Temp. Lt. (Acting Maj.) H. Goodman, R.A.M.C.; Temp. Capt. (Acting Maj.) H. B. G. Russell, R.A.M.C.; Senior Asst. Surg. E. V. Duckworth, I.S.M.D.

RELEASED MEDICAL OFFICERS.

The following medical officers have been released from captivity in Turkey:—

R.A.M.C.—Lieut.-Col. E. Bennett, Capt. J. S. Startin, Capt. T. E. Osmond, Capt. E. G. S. Cane.

I.M.S.—Lieut.-Col. E. F. E. Baines, Maj. S. G. S. Haughton, Maj. W. M. Pearson, Capt. C. Newcomb, Capt. M. L. Puri, Capt. L. A. P. Anderson.

FIRST BRITISH AMBULANCE UNIT FOR ITALY.—The value of the unit's work, which is to terminate at the end of the year, has been publicly recognised by the Italian Red Cross in the award of three *Croce Rossa* silver medals with certificates, one of them to Dr. George S. Brock, who was for a long time in medical charge of the Villa Trento Hospital, at Gorizia. The unit, after many stirring episodes, lays down its work in the now Italian seaport of Trieste.

OBITUARY OF THE WAR.

ROGER DAWSON BROWNSON, B.A., M.B., B.C. CAMB.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain R. D. Brownson, who died at Peshawar on Oct. 21st, was only son of the Rev. F. Brownson, of Compton Greenfield, Gloucestershire. He was educated at Warwick and St. John's College, Cambridge, going on to the London Hospital. He took the Conjoint diplomas in 1908 and the M.B., B.C. Camb. in 1911. For two years he practised at Hampstead, and on the outbreak of war he volunteered for active service and received a commission in the R.A.M.C. In February, 1915, he was sent out to France, where he was attached to the 1st Norfolks, and while with them he was gassed. After recovery he was given home service with an R.E. Bridging Train at Plymouth. In January, 1916, he was sent to India, attached to the King's Own at Peshawar, where he soon became Staff Surgeon, an appointment which he held until his death, which was the result of influenza. Captain Brownson was a keen sportsman and a regular follower of hounds at Peshawar. He married in 1911 the Hon. Gwenllian Rice, third daughter of the late Lord Dynevor, and leaves a widow and one daughter 3 years old.

FRANK PEARCE POCOCK, M.R.C.S. ENG.,

DISTINGUISHED SERVICE ORDER, MILITARY CROSS, TEMPORARY SURGEON, R.N.

Surgeon F. P. Pocock, who died of wounds on Sept. 29th, at the age of 27 years, was younger surviving son of Charles Wellesley Pocock, of Portishead. He was born at Harrow and educated at Durston House, Ealing, Ripley Court, Surrey, and St. Paul's School, where he gained an open scholarship to Westminster Hospital. He qualified M.R.C.S. Eng. in 1913 and then held the post of house surgeon at his hospital. On the outbreak of war he offered his services to the Navy, and for the first 14 months was posted to a battleship on the North Sea. He was then transferred to the Royal Naval Division and saw service in the Eastern Mediterranean and afterwards in France as M.O. to the Drake Battalion. In the autumn of 1916 he was awarded the M.C. He was invalided home in November, 1917. He served with the Royal Marines as surgeon on *Iris II.* in the Zeebrugge raid of April last, and for his services on this occasion was awarded the D.S.O. He returned to the Drake Battalion in August as M.O., and was mortally wounded himself as he was going to the assistance of a wounded man. Letters from his friends indicate the affection and esteem in which Surgeon Pocock was held. An old college friend writes: "He was one of the most popular and best-loved men who have been through the hospital for many years."

GEOFFREY ALWYN GERSHOM BONSER, B.A. CAMB., M.R.C.S. ENG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain G. A. G. Bonser, who was killed in action in France on Sept. 29th at the age of 30 years, was only son of G. G. Bonser, J.P., of Sutton-in-Ashfield. Educated at Brighton College and Worcester King's School, he entered St. John's College, Cambridge, taking honours in the Science Tripos, and going on to St. Thomas's Hospital, London, for his clinical work. His tastes were literary and poetical, with a passionate love of music, and while at St. Thomas's he edited the hospital gazette. After obtaining the diplomas of the Conjoint Board he joined the Territorials in 1915 while preparing for the Third M.B. Examination at Cambridge, and was attached to the Eastern General Hospital, assisting the staff at Addenbrooke's Hospital until he sailed for Egypt on Easter Day, 1916. There he served on both fronts, going through many hardships in the Palestine campaign and spending Christmas in Jerusalem. Last May he was transferred to France, and coming home on leave for the first time in July he was married to Miss Lilian Prime, to whom he had long been engaged. Two months after his return to France he was killed instantaneously by a shell while attending wounded. A letter from his colonel contains the sentence: "Captain Bonser's death is a great loss to the battalion; from all who knew him well I have heard nothing but praise." The utmost sympathy will be extended to his young widow.

KENNETH McALPIN ROSS, M.B., CH.B. GLASG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain K. McA. Ross, who died of wounds on Sept. 17th at the age of 26 years, was second son of the late Dr. William Ross, of Glasgow, and was educated at Bellahouston Academy, where he was a prominent swimmer and footballer. He graduated M.B., Ch.B. at Glasgow University in 1915, immediately obtaining a commission in the R.A.M.C. He went out to France in the following year as medical officer to a battalion of Lancashire Fusiliers, and was invalided home in 1917. In the present year he volunteered again for service, and in July was attached to a Scottish regiment, with which he received a fatal wound at Moevres. He leaves a widow and a wide circle of friends to lament his loss.

Captain JAMES GRANT MACNEILL, *M.C.*, C.A.M.C., who was killed in action on Oct. 12th, was 25 years of age and a native of St. Stephen, N.B., Canada. He graduated in medicine at Queen's University in 1916 and left Canada in May of that year. Crossing to France in August, 1916, he served with a field ambulance and as regimental M.O. He was awarded the Military Cross last July.

GEORGE FINCH, M.R.C.S. ENG., D.P.H. OXF.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

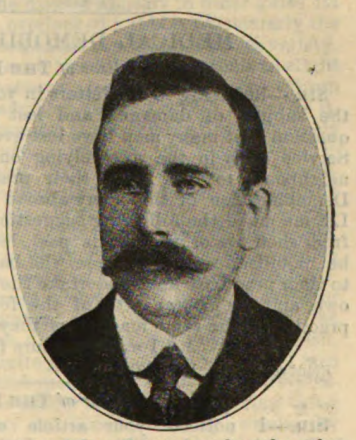
Captain G. Finch, who died at Basra on Oct. 8th, aged nearly 46 years, was only son of the late George Finch, of Kensington. He was educated at Bedford Grammar School and at Weimar, studied engineering at University College, London, and afterwards was engaged on the construction of the Central London Tube Railway. An illness turned his thoughts towards medicine, and he began a medical course at Leeds University, finishing it at St. Thomas's Hospital, London, from which he took the Conjoint diplomas in 1905. Five years later he obtained the D.P.H. Oxford. After a series of resident hospital appointments in London he was appointed in 1911 school medical officer for the East Sussex County Council. When war broke out he was assistant to the county medical officer of health for East Suffolk and resided at Ipswich. He immediately volunteered and received his commission in the R.A.M.C. before the end of the first week of the war, and was attached to the 3rd East Anglian (Howitzer) Brigade of the R.F.A. (T.F.). Later he was transferred to the military side of St. Thomas's Hospital, and thence to the 3rd London General Hospital, Wandsworth. In July, 1916, he was one of the hospital unit chosen for Mesopotamia by Colonel Bruce-Porter. Shortly after arriving at Basra he was appointed port health officer there, and held this appointment until his death from pleuro-pneumonia in the officers' hospital.

Captain Finch's heart was in his public health work, evidence of which may be seen in his contributions on school inspection and on the feeding of infants and children in the *Child* and in our own columns. He leaves a widow, the second daughter of Professor G. Carey Foster, F.R.S., and a daughter 2 years old.

GIDEON HENDRIK VAN ZYL, L.R.C.P. EDIN.,

LIEUTENANT-COLONEL, SOUTH AFRICAN MEDICAL CORPS.

Dr. G. H. van Zyl, who died of pneumonia at Wynberg in his forty-second year, was son of the late William van Zyl. He was educated at Robertson and Wellington High Schools and at Edinburgh, where he took his medical diplomas before returning to South Africa, where he started in practice at Zand Vliet, in the district of Robertson, in September, 1905. Dr. van Zyl was a diligent citizen of Robertson; he was on the executive of the local agricultural society and a member of the Turf Club and Masonic Lodge. He married in June, 1905, Frances, daughter of the late Edward Allsopp, by whom he had two children.



Captain THOMAS REGINALD GUILFOYLE, C.A.M.C., who died on Oct. 29th, at the age of 26 years, was a native of Lucan, Ontario. He graduated in medicine at the Western University, London, Ontario, in 1914, and came to England in July, 1916, serving with a stationary and a general hospital in England until last February, when he was invalided back to Canada. He returned again to duty in England in July, serving as S.M.O.

Correspondence.

"Audi alteram partem."

THE MEDICAL SERVICE OF THE ROYAL AIR FORCE.

To the Editor of THE LANCET.

SIR,—With reference to the annotation under the above heading in your issue of Nov. 16th, it may be pointed out that as the period of compulsory service for medical men in the armed forces is now drawing to a close it will be necessary to obtain some definite statement as to the above service if medical men of ability are to remain in it or be attracted to it. A scheme for this service drawn up by the Medical Advisory Committee of the Flying Services still holds the field, although it has not yet been called on for active duty while the "duration of the war" compromise known as the Medical Administrative Committee has ceased to exist.

It should be made widely known that the scheme of the Medical Advisory Committee was designed *pro bono publico* and not *pro bono medico*. At the same time, it was kept in mind that an efficient medical service for the Air Force could only be carried on by efficient medical men. So far the principles of the scheme have met with general approval, but the only application of them has been as a soothing syrup for anxious inquirers in the House of Commons. Nine months ago Major Baird, Under-Secretary of State for the Air Ministry, expressed the hope that the newly appointed Medical Administrative Committee would be able to carry out the principles of the scheme. A fortnight ago he expressed the hope that the newly appointed Director-General would be guided by the principles of the scheme. Major Baird's hopefulness is no doubt useful in Parliament but does not help members of the medical profession desirous of joining the Air Force, and they will be well advised to wait until it is known whether the Air Board have definitely adopted and guaranteed the principles of the scheme.

An important recommendation in the scheme was the appointment of a Medical Advisory Committee, meeting once a month, to aid the Director-General. It was to consist of the Director-General, his chief medical officers, and a strong civilian element. Although the functions of this committee were to be advisory only its influence in securing a high standard of professional work promised to be very great. The presence of experts on medical subjects drawn from the civilian population would undoubtedly strengthen the hands of the Director-General in maintaining an up-to-date medical service.

I am, Sir, yours faithfully,

Wimpole-street, W., Nov. 17th, 1918. G. A. SUTHERLAND.

MEDICAL DEMOBILISATION.

To the Editor of THE LANCET.

SIR,—Referring to the letters in your issue of Nov. 9th on the subject of damaged and lost practices, it is beyond question that many men have lost everything by joining the Service early in the war, relying on their "indispensable" neighbours to look after their practices in their absence. Demobilisation of the Army abroad will take many months. Let me make the following suggestion: Now that all danger from shell fire or gunshot is past, let the "indispensables" be mobilised to release those who have served long to return to their practices and undertake the reconstruction of their own and the looking after of the former "indispensables'" practice in the same manner as they have been "done" by.

I am, Sir, yours faithfully,

Pembroke, Nov. 12th, 1918. A. HURRELL STYLE.

To the Editor of THE LANCET.

SIR,—I noticed your article of recent date which dealt with the demobilisation of the medical services. I gathered that the principle to be adopted was to demobilise those who have had the longest service, and those who joined the services last were to be retained until the last. I agree that in many ways this is a good method to adopt, but I cannot accept it as by any means the fairest and most just.

I would point out most emphatically that there are a large number of medical officers in the R.A.M.C. who have done long service at the base and on lines of communication in comfort and ease. These medical officers have had all the advantages of hospital appointments and have been able to retain their medical and surgical knowledge, and, most important, have kept their methods up to date. On the other hand, there are a very large number of medical officers who have spent the greater part if not the whole of their service in the front areas with field ambulances and regiments. These medical officers (in contrast to their more fortunate brothers at the base, &c.) have had all the discomfort of the front line and dangers of the battlefields. Above all, they have been entirely cut off from the medical world, and have most naturally lost much of their former knowledge, as the medical work in the front areas consists almost entirely of first aid and evacuation of wounded and the treatment of slight sickness.

I think without a doubt that no one could disagree that these latter medical officers with front-line services to their credit should be demobilised before those with base-work service. In writing to you I am voicing the opinion of many others, and I feel sure that those responsible will fully consider this aspect with every care.

I am, Sir, yours faithfully,

France, Nov. 18th, 1918. LONDON.

To the Editor of THE LANCET.

SIR,—All temporary and Territorial officers of the R.A.M.C. who have been serving abroad will surely endorse the view put forward by "Lieut.-Colonel, R.A.M.C. (T.F.)" in the letter which appears in your issue of Nov. 9th. Eminent consultants, who will have an assured position under any conditions of State service, are surely not the best advisers as to what form such a scheme should take. Those who have left their practices to serve should be assured of a good billet when peace is signed. Even in that case they would lose the capital value of their practices, whilst those medical officers who have been able—as many officers of the T.F. have—to attend to their practices whilst performing their military duties are not under the same disadvantages.

Some steps should certainly be taken to recompense medical officers who have been compelled to leave their practices, through their own patriotism, for the unenviable position in which they will find themselves after the war, and under any scheme of State service they should have preferential treatment.

I am, Sir, yours faithfully,

Nov. 12th, 1918. TEMP. CAPT., R.A.M.C.

THE ETIOLOGY OF INFLUENZA.

To the Editor of THE LANCET.

SIR,—For some time previous to the appearance of the epidemic in Reading I have had occasion to examine many sputa from men who had been "gassed" in France. These sputa were generally submitted to culture, and in the course of this work it became evident that one particular type of organism was occurring with almost mechanical frequency. Since the epidemic broke out in this neighbourhood I have recovered apparently the same organism in pure culture from the blood of a patient with practically no physical signs in the chest, from the pleural fluid of another case, and I have isolated it from a throat swab culture as well as from sputa from civilian cases.

One case, however, which came under my notice seems to me to possess a special interest. The patient was said to have had an attack of influenzal broncho-pneumonia on the way across from America. While convalescing near Reading he suddenly developed a temperature and was admitted under the care of my colleague, Major G. S. Abram, R.A.M.C. (T). The patient had enlarged glands in both groins and in the left axilla without any obvious local irritation to account for them. The possibility that it might be a case of plague presented itself, and I was asked by my colleague to make a bacteriological investigation. From one of the glands I extracted a few drops of blood-stained fluid with which I inoculated two guinea-pigs intraperitoneally. The animals remained fairly well for a week, but were found dying on the eighth day. One of them had apparently been passing blood, as its hind parts were blood-stained. On making a post-mortem examination I found the peritoneal cavity of each

animal to contain a large quantity of blood-stained fluid. Cultures made from these animals have yielded a pure growth of an organism apparently identical with that found in influenzal and in "gassed" cases. There was no evidence of true plague.

In another case, as the sputum contained pestis-like organisms, I again inoculated guinea-pigs. One of them was found dead in 48 hours with acute general peritonitis. Cultures made from the heart blood and from the peritoneal fluid yielded a pure growth of the organism under discussion. Films made from the peritoneal fluid, however, showed enormous numbers of Gram-positive diplococci, apparently capsulated and resembling pneumococci. They differed however, in being larger, less pointed, and more of an ovoid shape.

The organism has the following characteristics:—

It grows well on agar containing sheep's washed blood corpuscles and in blood-glucose broth. On the former the colonies are round, slightly dome-shaped, translucent, and posse-s a sharply defined outline. They are very minute, and a hand lens may be necessary to enable them to be examined. Where they are less closely sown the colonies are larger and distinctly flat, and show considerable variation in appearance. Some possess a central depression of varying size, others present an even surface, while still others show a central eminence. Broth is rendered turbid and contains very tiny flocculi, which do not altogether disappear on shaking.

In films made from blood agar or from blood broth the organism shows considerable diversity of form. Very long chains predominate. These are composed of diplococci, ovoid rather than lanceolate-shaped. In the course of a chain may be seen other coccal elements, reminiscent rather of a large size of catarrhalis than of pneumococci. Isolated diplococci of both types are numerous and possess an apparent capsule. Involution forms are common—e.g., giant cocci, balloon-shaped forms, and even bacillary types. The latter, however, can frequently be seen to be actually made up of coccal elements which have remained united. Young cultures and cultures made on blood media stain very intensely with Gram's stain, but in certain media they rapidly lose this power, passing through an intermediate stage in which Gram-positive and Gram-negative elements exist side by side and even in the course of the same chain, and finally become for the most part frankly Gram-negative. In the latter stage forms can be seen which bear a distinct resemblance to the bacillus of plague. This is interesting when we remember that pestis-like forms may be seen in sputum films. The Gram-negative elements soon become mis-shapen, stain feebly with the counter-stain, and appear to be in process of dissolution. What determines these rapid changes I have not yet decided, nor have I worked out all the cultural characters. The organism does not appear to be a typical pneumococcus nor yet a typical streptococcus, although it resembles each in certain particulars. Its behaviour in culture gives one the impression of its being highly unstable owing to the rapid changes in its morphology and staining power. This may account for the fact that it is difficult to find the organism in stained films made from sputa, as it does not exist there, as a rule, in the typical form met with in cultures, but, having once studied the forms in laboratory culture, it is not difficult to recognise fairly accurately when the organism is present. This can only be accurately determined, however, by culture.

The fact that this organism has been got from the sputum of practically every case examined here as well as from the blood, &c., and in the absence of any other organism common to all, renders this organism worthy of being regarded as the possible etiological factor. A study of its somewhat erratic morphological changes, &c., furnishes a reason why it has not received more attention, especially as in many instances the sputa are merely examined microscopically, and without an idea of its cultural characters it might be difficult to trace a definite bacterial connexion between various sputa. In view of the tendency to hæmoptyses and to epistaxis, characteristic of many cases in this epidemic, the post-mortem findings in the case of the guinea-pigs inoculated with gland juice seem somewhat significant. Mixed sensitised vaccines containing amongst other things some of this particular organism have been used in treatment with good results in several cases. It now remains to be seen if a sensitised vaccine made from this organism alone will influence cases of the so-called influenza where no apparent respiratory trouble exists.

The work is only fragmentary at present, but enough has been done to justify to some extent the claim to consideration which I make on behalf of this particular organism, which for the time being we may call a pneumo-streptococcus. In view of the urgency of the occasion I feel that others who are working on the problem of the epidemic may have the opportunity to corroborate or otherwise my findings. Pfeiffer's bacillus I have generally found to be absent, and if the causal factor were a filter-passer, while the secondary complications were due to streptococci or pneumococci, why should one particular type of organism having the characters I have already mentioned be so invariably present?

I am, Sir, yours faithfully,

ROBERT DONALDSON,
Pathologist, Royal Berkshire Hospital.

Reading, Nov. 12th, 1918.

VARIETIES IN INFLUENZA.

To the Editor of THE LANCET.

SIR,—May I call attention to a few facts which, taken together, appear significant?

(1) The present pandemic of influenza is characterised especially by pulmonary symptoms.

(2) Pandemics of a malady clinically very similar have occurred at intervals of about a generation for many hundreds of years. There was one in 1890, and another in 1847.

(3) If my memory serves me right, this type of influenza lingered in rapidly diminishing epidemics for a very few years after 1890. It was subsequently replaced by annual, very minor, and clinically very different epidemics, in some of which the pharynx and nose were especially affected. Early in the summer of the present year an epidemic occurred among troops in my charge. Hundreds of men were affected, but none showed any symptoms beyond the ordinary accompaniments of pyrexia (rigors, headaches, and the like). All recovered within a week.

(4) The 1890 pandemic differed strikingly from the present one in that, while in 1890 people of all ages were equally attacked and elderly people perished in great numbers, in the present epidemic elderly people have very generally escaped.

If the foregoing is correct it seems probable (*a*) that under the term "influenza" are grouped not several types of the same disease, but several distinct diseases; and (*b*) that one attack of that disease which has occurred in great pandemics (and which is that described in the text-books as "influenza") confers on the individual an immunity which is usually permanent. I do not know how else can be explained the very unlike clinical manifestations of the minor epidemics, or the fact that in the present pandemic, which is separated from its predecessor by 28 years, elderly people have been very generally spared, whereas in the 1890 pandemic, which was separated from its predecessor by 43 years, elderly people suffered severely.—I am, Sir, yours faithfully,

G. ARCHDALL REID.

Southsea, Nov. 17th, 1918.

THE APOPLECTIFORM VARIETY OF EPIDEMIC ENCEPHALITIS.

To the Editor of THE LANCET.

SIR,—One clinical variety of epidemic encephalitis, although mentioned by some of the speakers in the discussion at the Royal Society of Medicine, appears hardly to have received the attention which it deserves. The "new syndrome," in which lethargy or stupor and plastic tonicity of the muscles are combined with palsy of the ocular, facial, or other cranial nerves, is sufficiently well known to ensure its recognition. When the disease appears in other guise its true nature is apt to be overlooked; this is particularly the case with what may be designated the apoplectiform variety. In this—sometimes after such prodromal symptoms as slight headache or malaise, sometimes after a premonitory seizure which in minor degree resembles the one which succeeds it, sometimes without any warning at all—the patient, suddenly stricken down with agonising pain in the head, becomes collapsed and unconscious. The seizure may be accompanied by vomiting, twitchings of the limbs, or epileptiform convulsions, but this is not always the case. Unconsciousness lasts a variable period, but is not necessarily prolonged. On recovery, patients have likened their pain to a sudden blow with a stick on the occipital region or inside the head. After subsidence of the acute symptoms of onset an extensor response may often be obtained from one or both soles, the abdominal reflexes may be absent, and the pupils sluggish, sometimes unequal. Definite paralysis of the limbs and face may occur. Curious disturbances of the pulse and respiration may be present in the earlier stages, the breathing being alarming in its infrequency and accompanied by yawning, or definitely of the Cheyne-Stokes type. The pulse may be slow or rapid or irregular, with numerous extra-systoles. The blood pressure may show such wide variations within a few moments that its determination is impossible. Forced attitudes are noticeable in some, the head being forcibly deviated towards one or other shoulder and kept in this position. Rushing noises in the ears, vertigo, apparent movement of external objects, and dimness of vision may one or all be present, but apparently subside very soon. Incontinence of fæces and urine has been observed. Fever is often present and transient albuminuria, sometimes in marked

degree. The fluid obtained by lumbar puncture shows no undue pressure, but traces of blood are too constantly present to be accidental. Sometimes there is a lymphocytosis in addition. In favourable cases recovery may occur very rapidly, so that the patient is about again in a few weeks.

The symptoms of onset clearly suggest cerebral hæmorrhage, and post-mortem examinations show that, in some instances at all events, this has occurred. When we bear in mind the frequency with which hæmorrhagic foci are combined with the perivascular lymphocytic infiltration of epidemic encephalitis, the occurrence of vascular symptoms is not surprising. Some of the specimens examined suggest that the gross lesion may at times be rather of the nature of a hæmorrhagic infarction than a true extravasation, and it is conceivable that the perivascular exudation might itself lead to vascular strangulation or thrombosis. The hæmorrhagic foci in the fatal cases appear to originate in the grey matter, and have been found, sometimes in the cerebral cortex, sometimes in the vicinity of the basal ganglia, sometimes in the brain stem, and occasionally in the cortex or dentate nucleus of the cerebellum. These cases are likely to be confused with cerebral hæmorrhage of the ordinary type, but are mostly distinguished from this by the age incidence and by the absence of any signs of cardio-vascular degeneration or of chronic renal disease. The cerebral hæmorrhage of ulcerative endocarditis and of hæmorrhagic blood conditions may be excluded by the absence of the physical signs of these diseases. Moreover, the epidemic cases tend to occur when encephalitis of other types is prevalent, and show in many instances a decided tendency to spontaneous recovery.

I am, Sir, yours faithfully,

Devonshire-place, W., Nov. 16th, 1918. CHARLES R. BOX.

EXAMINATIONS FOR AMŒBIC DYSENTERY INFECTIONS.

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 16th, which has recently come to hand, there appears a letter by Mr. Clifford Dobell criticising some observations of mine on the results of an investigation on *Entamœba histolytica* infections among British troops in India and Mesopotamia, a full report of which had appeared in the *Indian Journal of Medical Research*, 1917, vol. v., p. 239, and a précis of which had been published by you in your issue of Jan. 5th last. Mr. Dobell's criticism is almost wholly directed to the deductions I have drawn from the figures of his statistical essay published by the Medical Research Committee,[1] as applied to the results of our inquiry conducted on troops of the Mesopotamian Field Force. Nothing was further from my intention than any misinterpretation of his figures, and I feel indebted to Mr. Dobell for having taken the time and trouble to point out what he conceives to be their misuse and their application under conditions which, in his opinion, no longer render them admissible.

The main point at issue turns on the fact that while Mr. Dobell's figures are confined to the question of how many protozoological examinations are required to discover all cases of infection, my remarks were directed to the number of examinations required to detect merely cases of *heavy* infection. The curve showing the rapid decline in the percentage of positive findings obtained after three examinations per case, to which Mr. Dobell takes exception as completely misinterpreting his figures, appears, however, to obtain his explicit approval where he says; "When only some three examinations per case are made, those cases which pass cysts regularly are detected and those which are frequently negative, are overlooked" (p. 40[1]). And this to my mind is the only question of practical importance when dealing with a body of men among whom small or intermittent infections were found to be so common in the detection and segregation of the *gross* carriers.

No one will differ from Mr. Dobell when he says that it is impossible to state precisely, as a result of examining only single samples from a series of cases, what the real incidence of infection is, and my use of the term "Dobell's figures for correction" doubtless tends to clothe the figures with a mathematical accuracy which is unwarranted. However, Mr. Dobell, by very careful deduction and analogy, had come to the conclusion: "The chances against detecting the infection by any one examination of the *average* infected case are nearer 2:1 than 3:2" (p. 42). I felt myself justified in making use of his lower figure in calculating that in a series of cases in which 13·6 per cent. of infections were detected by one examination, the true incidence of infection was approximately 34 per cent. It has to be remembered that those examinations and the deductions therefrom were made at a time when none of the papers on the carrier question as it affects the tropics had been published, and an official request had been made to me for an opinion on the disposal of such cases. The positive findings obtained on the single examination method were so numerous that more frequent examinations per case of the non-dysentery patients were not required to prove how general *histolytica* infection was among the men being invalided from Mesopotamia for other than intestinal diseases, and how futile it was to attempt to deal with any but the gross type of carrier.

Although the factors to be considered in regard to the clearing of *histolytica* infection in England may be somewhat different from the conditions of the tropics, Mr. Dobell will no doubt agree with me as to the marked effects of diet and conditions of life in leading to a return of intestinal irritation and to the possible reappearance of cysts in the stools. Hence the importance of "clearing" patients when living under other than hospital conditions. It was to direct attention to such details that a considerable portion of my criticism was intended, because, as I think my results conclusively prove, the conditions of life under which potential carriers are living at the time of examination appear to be of greater importance than the actual number of examinations carried out.

I am, Sir, yours faithfully,

On Service in the Far East, May 26th, 1918. WM. MACADAM, Captain, R.A.M.C.

[1] Medical Research Committee, Special Report Series No. 4, 1917.

THE SEXUAL COMPLEMENT.

To the Editor of THE LANCET.

SIR,—Your leading article on the sexual complement which appeared in THE LANCET of Nov. 16th raises many questions of great biological and clinical interest. As you have stated, the profound mental and physical modifications which in many women follow quickly upon marriage are matters of common observation. They are attributable to the altered life attendant on the married state, which involves change of action and environment each moment of the day from one sunrise to the next. It is beyond the skill of man to apportion justly amongst the several elements of change introduced the various modifications which are wrought. Is it not possible, however, to separate from the complex something which is due to the action of the prostatic secretion on the woman?

Your leading article aptly marshalled the knowledge of the physiologist and comparative anatomist but ignored completely the evidence to be found by clinical observation. Medicine owes great debts to physiology, especially in the domain of internal secretions, but at various times portions of the debt have been repaid. We should know but little of the action of the thyroid gland on the eyebrows or on the subcutaneous tissue had we relied solely on laboratory studies of health. It was only by its therapeutic administration in disease that the gland was seen to stimulate scanty eyebrows to luxuriant growth and to reduce thick myxœdematous tissues to due proportions. This is only one of many instances in which clinical medicine has lightened the dark places of physiology.

When the prostate gland substance, in tablet form, is taken by the mouth by unhealthy women quite definite results follow. Normal breast tissue is soft and of a velvet-like consistency. Such breasts are not common amongst women with systemic disease. With the development of even minor degrees of chronic intestinal stasis the mammary tissues begin to feel granular when palpated between the fingers and thumb, and are tender at the menstrual epoch. After a time the hardening becomes greater, the granularity coarser, and the tenderness more continuous, until the condition is recognised as chronic mastitis. Sir Arbuthnot Lane described this sequence many years ago, and more recently in his article in THE LANCET of Nov. 9th, where he also pointed out that the prostate gland has the power of diminishing the granularity and of abolishing the pain and tenderness of such breasts. Of this fact there can be no doubt, because the effect is pro-

duced even when the prostate is administered by the mouth in tablet form. The evidence is not merely that of an altered symptom, but also that of an altered physical sign observable by simple palpation. One of the most convincing cases which I ever observed was that of a woman whose breasts were so tender that she dreaded to enter any crowded place because of the intensity of the pain induced by any slight accidental pressure. I gave her dried prostate gland in tablet form, and the condition was completely controlled. After a time she ceased to take the tablets continuously and used them only when tenderness threatened to recur.

The secretion of the male organ is, therefore, clearly useful to the diseased female in this respect. It seems justifiable to suggest by analogy that it is capable of effecting other changes in other tissues and may be responsible for the improved state of nutrition and many other chemical and structural changes which follow upon the consummation of the sexual functions. A most fascinating biological principle is thus vindicated. The prostate gland stands pre-eminent as an organ found in one sex only, but producing a secretion needful to the complete well-being of the opposite sex, an organ possessed by one to be shared by two, and serving as a biochemical keystone linking complement to complement. I am, Sir, yours faithfully,

London, W., Nov. 16th, 1918. N. MUTCH.

RECONSTRUCTION IN NEUROLOGY.

To the Editor of THE LANCET.

SIR,—In the annotation under this heading in your issue of Nov. 16th you observe that Dr. Aldren Turner stated in his paper on the Neuroses of the War that all neuroses are the consequence of a failure of psychological adaptation. The wording suggests that Dr. Turner is responsible for this view, and I am sure that it was not intended to convey this meaning. The view that neuroses are failures of adaptation is one that was coming to the forefront long before the war started. I quote the following observation of Dr. Jung, in a paper read before the Seventeenth International Medical Congress in London, 1913:—

"The psychological trouble in neuroses, and neurosis itself, can be considered as an act of adaptation that has failed. This formulation might reconcile certain views of Janet's with Freud's view that a neurosis is—under a certain aspect—an attempt at self-cure; a view which can be and has been applied to many diseases."

I am, Sir, yours faithfully,

MAURICE NICOLL.

Empire Hospital for Officers, Westminster, S.W., Nov. 16th, 1918.

*** Captain Nicoll is right in believing that our words were not intended to make any such claim.—ED. L.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

To be temporary Surgeon-Lieutenants: J. H. Sheldon, J. T. Johnston.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. H. P. W. Barrow relinquishes the temporary rank of Colonel on re-posting.

Temp. Major R. H. Cooper and Capt. F. C. Moore to be temporary Lieutenant-Colonels whilst specially employed.

Temp. Capt. W. B. Davy to be acting Major whilst specially employed.

To be acting Lieutenant-Colonels whilst in command of a Medical Unit: Temp. Capt. (acting Major) F. R. Thornton, Lieut. (temp. Capt.) A. J. Hickey, Temp. Capt. L. G. Brown, Temp. Major C. V. Mackay, Major F. A. Stephens.

Temp. Capt. H. Dodgson to be temporary Major.

To relinquish the acting rank of Major on re-posting: Temp. Capts. H. F. Wilson, W. S. Martin, T. P. Cole; Capt. E Catford.

To be acting Majors: Temp. Capts. D. MacIntyre, H. J. Pickering, C. S. E. Wright, R. G. Riches, J. S. Hall, G. H. Darlington and P. A. Leighton (whilst specially employed), W. A. Clayton (whilst commanding troops on a Hospital Ship); Capt. D. C. G. Ballingall.

Lieutenants (temporary Captains) to be Captains: J. M. McKenzie, R. R. Thompson, (acting Major) A. E. Richmond, (acting Lieutenant-Colonel) A. J. Hickey.

Temporary Lieutenants to be temporary Captains: J. B. J. L. Dalby, F. G. Beatty, J. Walker, H. A. R. E. Unwin, A. Y. Hutchison, D. A. H. Moses, E. Evans, C. Watson.

A. D. Clinch, late temporary Captain, is granted the honorary rank of Captain.

Temp. Capt. B. H. Mellon, from A.V.C., to be temporary Captain.

Officers relinquishing their commissions: Temp. Capts. W. H. Wishart (on account of ill-health, and is granted the honorary rank of Captain), V. G. Best, T. B. Sellors, P. A. Hall, G. R. Gray, J. Welsh (on account of ill-health contracted on active service, and is granted the honorary rank of Captain).; Temp. Hon. Lieut. S. A. Moor.

The undermentioned on transfer to R.A.F.: Temp. Capts. W. H. Anderson, F. H. Bowen, E. Brown, J. D. Bridger, E. R. Bastard, L. C. Blackstone, W. Bannerman, J. E. Cable, J. E. Cox, E. P. Chennells, E. P. Carmody, G. W. Clark, L. G. Davies, A. J. Davoren, R. H. Dixon, R. A. G. Elliott, J. Gardner, H. M. Holt, P. H. Hadfield, H. Harvey, R. J. Hearn, A. E. F. F. Huntsman, T. R. Hunter, F. Irvine, F. C. Jobson, W. M. Jeffreys, J. Keenan, W. R. Kemp, A. Lindsay, E. W. Longden, W. B. Loveless, G. Lewin, C. E. Lowe, T. E. Mulvaney, F. C. Morgan, A. E. McCulloch, P. W. McKeag, W. R. Nasmyth, H. J. Ranken, J. J. Sinclair, H. B. Smith, C. Salkeld, J. B. Stevenson, A. E. B. Sim, W. A. Simpson, F. O. Spensley, C. E. Thwaites, A. Thompson, C. Visger, A. W. Weston, A. J. O. Wigmore, D. Wilson, J. L. Whatley, W. F. Walker, H. E. Whittingham, H. N. Wright, L. A. Walker, W. P. Wippell, A. H. Wade, M. R. Dobson, M. Hocken, O. May, C. Peacock, C. P. Strong, A. H. L. Thomas; Temp. Lieuts. C. J. Miner, C. T. Costello, J. A. Johnson, P. M. Roberts.

Queen Mary's Army Auxiliary Corps.

To be Controllers of Medical Services: Jane H. Turnbull, Laura S. Sandeman.

To be Medical Controllers: Irene C. D. Eaton, Mabel A. D. Crawford, Cicely M. Peake, Grace E. Soltau, Mary G. McCullough, Katherine J. S. Clark, Alice Stalker, Eleanor E. Bourne, Agnes H. Nicholl.

To be Recruiting Medical Controllers: Adeline M. Roberts, Julia V. Christie, Anne M. Watson, Elizabeth Budd, Eleanor A. Montgomery, Hester M. Henderson, Mary B. Ferguson, Amy Hodgson, Charlotte A. F. Sturm.

To be Medical Officials: Hannah K. Alton, Marjorie McMullen, Celia M. C. Macneil, Amy F. Nash, Adeline H. Campbell, Alice Rattray, Stephanie P. L. H. T. Daniel, Margaret E. Douglas, Olive M. Anderson, Annie S. Robertson, Lilian M. W. Grant, Agnes M. Cowan, Rosalie Holmes, Hilda W. Esson, Jessie H. Gellatly.

SPECIAL RESERVE OF OFFICERS.

Major G. Lane is placed on the Retired List on account of ill-health contracted on active service.

Capt. R. L. Newell relinquishes the acting rank of Major on re-posting.

Officers relinquishing their commissions: Capts. R. G. Bannerman (on account of ill-health contracted on active service, and is granted the rank of honorary Captain) and D. Dempster (on account of ill-health caused by wounds, and is granted the honorary rank of Captain).

Captains to be acting Majors: A. F. L. Shields, A. Picken.

Lieutenants to be Captains: C. M. Titterton, R. N. Mackenzie, J. I. Watson, H. Taylor, C. Shaw-Crisp.

To be Lieutenants: J. M. Melvin and C. O. Anderson (from Glasgow University Contingent, O.T.C.), G. H. Middleton (from Edinburgh University Contingent, O.T.C.), S. E. Critchley (from Manchester University Contingent, O.T.C.).

TERRITORIAL FORCE.

Lieut.-Col. (Hon. Surg.-Col.) A. Thorne is retired on completion of tenure of command, and is granted permission to retain his rank and to wear the prescribed uniform.

Major A. J. Hall to be Lieutenant-Colonel and is restored to the establishment.

Major A. H. Buck relinquishes his commission on account of ill-health, and is granted the honorary rank of Major.

Capt. J. M. Bowie to be Major.

Temp. Capt. W. H. Broad to be Major (temporary).

Capt. J. P. I. Harty is seconded for duty with the R.A.F.

Capt. N. Milner is restored to the establishment.

Capts. L. Rawes, H. F. Everett, J. B. F. Wilson, J. McL. Macfarlane, and A. Rodger to be acting Majors whilst specially employed.

Capt. (temp. Major) F. D. S. Jackson relinquishes his temporary rank, and is restored to the establishment.

Capt. (acting Major) G. L. Chiene relinquishes his acting rank and is restored to the establishment.

Capts. F. M. Robertson and F. R. H. Laverick relinquish their commissions on account of ill-health contracted on active service, and are granted the honorary rank of Captain.

Capt. A. H. Evans is seconded.

Capt. (Brevet Major) H. F. Horne to be Major and to remain seconded.

Capts. E. T. Roper and M. W. Williams relinquish their commissions on account of ill-health, and are granted the honorary rank of Captain.

Capts. (acting Majors) W. T. Torrance and G. A. Auden relinquish their acting rank on ceasing to be specially employed.

Capt. F. C. Moore is seconded whilst holding a temporary commission in the R.A.M.C.

Capt. A. J. Walton is seconded for duty overseas.

TERRITORIAL FORCE RESERVE.

Capts. R. J. McConnell (from a Field Ambulance), N. P. Laing (from Attached to Units other than Medical Units), J. McG. Deuchars (from R.A.M.C.) to be Captains.

Canadian Army Medical Corps.

Temporary Captains to be temporary Majors: J. L. Tower, K. E. Hollis.

Temporary Captains to be acting Majors while specially employed: J. H. Moore (as Surgeon at a General Hospital), H. H. McIntosh (on X Ray Work).

INDIAN MEDICAL SERVICE.

Lieut.-Col. J. L. T. Jones is retired in consequence of ill-health.

Capts. C. R. O'Brien, N. H. Hume, and D. M. C. Church to be Majors.

ROYAL AIR FORCE.

Medical Branch.—Major (acting Lieut.-Col.) H. C. T. Langdon retains the acting rank of Lieutenant-Colonel whilst employed as Lieutenant-Colonel, from (S.O.). J. T. T. Forbes is granted a temporary commission as Lieutenant.

Dental Branch.—J. Jones and J. Wren are granted temporary commissions as Lieutenants.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An ordinary meeting of the Council was held on Nov. 14th, Sir George Makins, the President, being in the chair.—It was resolved that Diplomas of Membership should be granted to 94 successful candidates; also that Licences in Dental Surgery should be granted to 19 successful candidates.—Mr. William S. Haslam was re-elected a member of the Committee of Management.—In June last the President called the attention of the Council to the heavy rate of rejections at the Primary Examination for the Fellowship, to the dissatisfaction with which the examination was regarded by many, and suggested that it would be desirable to take into consideration the possibility of altering the subjects and character of the examination with a view to making it of more practical value as a test for surgeons likely to become chiefly engaged in operating practice. The matter was referred to the Nomination Committee, and a report from that committee was now presented, approved and adopted. It was to the effect that: (1) The Primary Examination for the Fellowship is an honours examination and should be continued as such; and (2) all the questions set should be relevant to the science of surgery.—The President reported that, in accordance with Article 6 of the Regulations for the award of Sir Gilbert Blane's prize medals, which provides that "if the unadjudicated medals should exceed four their value is to be given to the Supplemental Fund for the Children of Medical Officers," he had sent a cheque for £42, the amount of four years' income from the Blane Medal Fund, to the honorary treasurer, Naval Medical Compassionate Fund, Admiralty Medical Department, 12, Charles-street, Berkeley-square.—A letter was read from the Board of Scientific Studies forwarding a copy of a report by a committee of the Board favouring the introduction of a metric system of weights and measures in this country, and asking for the comments of the College in reference thereto. The consideration of this matter was postponed.—Sir George Makins and Sir John Bland-Sutton, were re-elected as representatives of the College on the Board of Scientific Studies for the year 1919.—The President reported that the vacancy on the Court of Examiners occasioned by the expiration of Mr. W. G. Spencer's term of office would be filled at the ordinary meeting of the Council on Dec. 12th. Mr. Spencer is not applying for re-election.—The President reported that he had granted the use of the lecture theatre on Nov. 13th, 20th, and 27th, and Dec. 4th and 11th, for five lectures by Dr. E. Mellanby, acting superintendent of the Brown Animal Sanatory Institute.

At the Primary Examination for the Fellowship, held on Nov. 6th, 7th, and 12th, 35 candidates presented themselves, of whom 15 (including six women) were approved and 20 were rejected. The following are the names and medical schools of the successful candidates:—

Arthur Silver Burns, McGill Univ.; Hetty Ethelberta Claremont and Edith Marian Evans, Lond. School of Med. for Women; Sidney Forsdike, Middlesex Hosp.; Ada Marion Freeman, Lond. School of Med. for Women; Henry Albert Harris, Univ. Coll.; George Franklin Wise Howarth, Middlesex Hosp.; Haji Hyderali Khan, Bombay Univ., Middlesex and Guy's Hosps.; Reginald Cyril Bell Ledlie, Guy's Hosp.; Sybil Grace Mocatta, Lond. School of Med. for Women; William George Rose, St. Mary's Hosp.; Harry Spibey, Cambridge Univ.; Mildred Warde, Manchester Univ. and Lond. School of Med. for Women; Agnes Edie Westwood, Lond. School of Med. for Women; and Frederick Arnold Williamson, Cambridge Univ. and St. Mary's Hosp.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of Comitia of the Royal College of Physicians of London on Oct. 31st and of the Council of the Royal College of Surgeons of England on Nov. 14th diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon 94 candidates (including 11 women) who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and have complied with the requisite by-laws. The following are the names and medical schools of the successful candidates:—

John Binford Barnett, Birm. Univ.; Lewis Henry Bartram, Camb. Univ. and St. Bart.'s Hosp.; Frederic James Bennett, Camb. and Manch. Univs.; William Leslie Berry, Camb. Univ. and St. Bart.'s Hosp.; Moshek Zelmanovitch Bochenek, Lond. Hosp.; John Clifford Brown, Birm. Univ.; John Maurice Brydson, Lond. Hosp.; Henry Cecil Herbert Bull, Camb. Univ., Lond. and St. George's Hosps; Frederick Thomas Burkitt, Camb. Univ. and St. Bart.'s Hosp.; Charles Reginald Cade, Guy's Hosp.; Duncan Campbell, New York Univ.; Walter Mattocks Casper, St. Bart.'s Hosp.; Cecil Belfield Clarke, Univ. Coll. Hosp.; Cyril George Coombs, Guy's Hosp.; Eric Ashley Crook, Oxford Univ. and St. Bart.'s. Hosp.; William Davies, Cardiff Univ. and Lond. Hosp.; Mary Day, Royal Free and St. Mary's Hosps.; Charles Cottrell Ralph Downing, Camb. Univ. and Univ. Coll. Hosp.; Clarence Franklin Eminson, Charing Cross Hosp.; David Washington Evans, Lond. Hosp.; John Harold Ewen, St. Mary's Hosp.; Paul Faraci, Beirut Med. Coll. and Middlesex Hosp.; Donald Charles Farquharson, St. Mary's Hosp.; George Annesley Fisher, Camb. Univ. and St. Bart.'s Hosp.; Lilian Mabel Fisher, Royal Free Hosp.; John Turnbull Thomson Forbes, Guy's Hosp.; Richard Gainsborough, Oxford Univ. and Guy's Hosp.; George Anthony Goolden, Camb. Univ. and St. Thomas's Hosp.; Lorne Benjamin Graham, Toronto Univ.; Clermont Grantham-Hill, Camb. Univ. and Lond. Hosp.; Denis Paul Guilfoyle, St. Bart.'s Hosp.; Albert William Holgate, Univ. Coll. Hosp.; Eric Theodore Holden, Birm. Univ.; Arthur St. George Joseph McCarthy Huggett, St. Thomas's Hosp.; Cori McColm Jones, Camb. and Liverp. Univs.; Robert David Jones, Liverp. Univ and St. Bart.'s Hosp.; Edward Gordon Joseph, Edin. Univ.; Florence Maltby Kerruish, Liverp. Univ.; James Kyle, Guy's Hosp.; Victor John Frederick Lack, Lond. Hosp.; Louis Jacques Maurice Laurent, Univ. Coll. Hosp.; Horace Sharman Le Marquand, St. Thomas's Hosp.; Allan Wellesley Lewis, St. Mary's Hosp.; George Strickland Lewis, Bristol Univ.; Sidney Simon Lindsay, St. Thomas's Hosp.; Tudor David Llewelyn, Cardiff Univ. and St. Thomas's Hosp.; George Lyon Lyon-Smith, Camb Univ and St. Bart.'s Hosp.; Hector Clive McAlister, Toronto Univ.; Kathleen McCrie McKeown, Royal Free Hosp.; Donald Gregory Macpherson, New Zealand Univ. and Univ. Coll. Hosp.; Walter Edgar Masters, Lond. Hosp.; Gordon Millar, St. Bart.'s Hosp.; Reginald Stanley Millar, Durh. Univ. and Guy's Hosp.; Arthur Richard Neckles, Guy's Hosp.; Wilfrid Otts, Camb. Univ. and St. Thomas's Hosp.; Harry Palmer, Lond. Hosp.; William Horson Palmer, Camb. Univ. and St. Thomas's Hosp.; *Aerath Narayanan Nanoo Pankker, Edin. Univ.; William Alfred Whitehouse Parkes, Birm. Univ.; Robert Hughes Parry, Middlesex Hosp.; Frederic Paul Nigel Parsons, Camb. Univ and Univ. Coll. Hosp.; Eugene Arthur Pearson, Lond. Hosp.; Evan Albert Idris Phillips and Montagu Cecil Polhill, Univ. Coll. Hosp.; Thomas Dawson Pratt, Leeds Univ.; Hubert Llewellyn Pridham, St. Bart.'s Hosp; Ronald Seton Ralph and Francis William Reitz, Guy's Hosp.; Theodore Ernest Roberts, Glasg. Univ.; Ronald Henry Ottywell Betham Robinson, Camb. Univ. and St. Thomas's Hosp.; Joan Margaret Ross, St. Mary's Hosp.; Charles Cecil Rowland, Lond. Hosp; Elizabeth Dill Russell, Royal Free Hosp.; Joseph Harold Shelton, King's Coll. Hosp.; Hilda Nora Shufflebotham, Birm. Univ.; Arthur Herbert John Smart, Camb. Univ. and St. Thomas's Hosp.; Frances Minnie Spickett, Royal Free Hosp.; Jacques Spira, Brussels Univ. and St. Thomas's Hosp.; Frank Hugo Stuttaford, St. Mary's Hosp.; Graham McKim Thomas, Guy's Hosp.; Edward Sherman Toogood, Univ. Coll. Hosp.; Norah Edith Trouton, St. Mary's Hosp.; Robert Hugh Turner, Bristol Univ. and Univ. Coll. Hosp.; Martin Baird Moore Tweed and Jacob Eliza De Villiers van der Merwe, Guy's Hosp.; Donald Wallace, Camb. Univ. and Lond. Hosp.; Hugh Pennefather Warren, Lond. Hosp.; †Thomas Digby Wheeler, Manitoba Univ.; Alice White and Ethel White, Sheffield Univ.; Julius Maurice Winnett, Lond. Hosp.; Geoffrey Winter, Birm. Univ.; Robert Wolff, Middlesex Hosp.; Sidney Carver Woodhouse, Lond. Hosp.

* M.R.C.S. Diploma alone conferred. † M.R.C.S. Diploma conferred on Oct. 10th.

NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES: GLASGOW BRANCH.—A course of lectures (illustrated by diagrams and lantern slides) will be delivered on the following Fridays, at 8 P.M., in the Berkeley Hall, Berkeley-street, Glasgow. Nov. 22nd: Professor F. O. Bower, F.R.S., Sex in Animals and Plants. Nov. 29th and Dec. 6th: Professor Thomas H. Bryce, F.R.S., Reproduction in Mammals. Dec. 13th: Professor Robert Muir, F.R.S., Microbic Infection in Venereal Disease. Dec. 20th: The Effects of Venereal Disease on the Body. Admission is free, and all engaged in teaching and social work are specially invited.

INFLUENZA IN LEICESTER.—The epidemic, which was of a very severe nature, now appears to be waning rapidly so far as fresh cases are concerned. Although the death-rate is still high, many of the deaths notified are of persons who have been seriously ill for some time. To combat the epidemic doctors and nurses usually connected with infant welfare, tuberculosis, and school inspection were diverted from their work. V.A.D. and other voluntary workers were also utilised. Some 60 beds were cleared at the isolation hospital by sending out scarlet fever and tuberculosis cases in order to provide the institutional treatment which was urgently needed, and over 70 cases have been treated there.

DONATIONS AND BEQUESTS.—The late Mr. James B. Dugdale, of Wareham, Dorset, has left by will £5000 to King Edward's Hospital Fund and £1000 each to the Dorset County Hospital and the Victoria Hospital, Bournemouth.—Under the will of the late Miss Emily C. Talbot, of Glamorgan, the testatrix has left £1000 each to King Edward VII.'s Hospital, Cardiff, the Swansea General and Eye Hospital, the University College of South Wales and Monmouthshire, and the Rest (seaside) Convalescent Homes at Porthcawl and Southerndown, South Wales; and £500 to the Gower Nursing Association of Queen Victoria's Institute for Nurses.—By the will of the late Mrs. Jessie M. Smith, of Pollokshields, the testatrix left £10,000 to the Glasgow Royal Infirmary; £5000 each to the Western Infirmary and the Victoria Infirmary, Glasgow; £2000 each to the Ayr County Hospital and the Royal Samaritan Hospital for Women, Glasgow; £500 each to the Glasgow Magdalene Hospital, the Mission to the Outdoor Blind of Glasgow and the West of Scotland, and the Glasgow Society for the Education of the Deaf and Dumb.—The late Mrs. Hannah Derbyshire, of Oldham, has among other legacies left £1000 to Oldham Royal Infirmary.—As a peace thankoffering Mr. W. T. Farr, of Mumbles, has given £5000 to the Swansea General Hospital.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The General Election.

THIS Parliament comes to an end this week, and a General Election will follow immediately. The voting takes place on Saturday, Dec. 14th. The counting of the votes is postponed until those recorded by the soldiers who are in Belgium and France can be received.

The War Casualties.

Mr. MACPHERSON, Under Secretary of State for War, stated last Tuesday that the figures available of the British casualties during the war were necessarily incomplete. Up to Nov. 10th, however, the following were the figures, including Dominion and Indian troops, for the various theatres of operations:—

Theatre of operations.	Killed (including died from wounds and died from other causes).		Wounded.		Missing (including prisoners).		Totals.	
	Officers.	Other ranks.	Officers.	Other ranks.	Officers.	Other ranks.	Officers.	Other ranks.
France...	32,769	526,843	83,142	1,750,203	10,846	315,849	126,757	2,592,895
Italy ...	86	941	334	4,612	38	727	458	6,280
Dardanelles ...	1,785	31,737	3,010	75,568	258	7,431	5,053	114,676
Salonika	285	7,330	818	16,058	14	2,713	1,217	26,101
Mesopotamia...	1,340	29,769	2,429	48,686	566	14,789	4,335	93,244
Egypt ...	1,098	14,794	2 311	35,762	183	3,705	3,592	54,261
East Africa	380	8,724	478	7,276	38	929	836	16,929
Other theatres	133	690	142	1,373	51	908	326	2,971
Totals ...	37,876	620,828	92,664	1,939,478	12,094	347,051	142,634	2,907,357

Grand total 3,049,991

The numbers "missing" include 6741 officers and 164,767 other ranks known to be prisoners of war, and also over 30,000 officers and other ranks whose deaths have been accepted for official purposes. In addition to the above figures there have been 19,000 deaths from various causes among troops not forming part of any of the Expeditionary Forces.

HOUSE OF LORDS.

WEDNESDAY, NOV. 20TH.

Prevention of Venereal Disease.

Lord SYDENHAM asked His Majesty's Government what steps were being taken to prevent the spread of venereal disease during and after demobilisation. He said that after previous wars this disease had entailed effects upon the civil population which were existing to this date. At the present time there were conditions which were even more favourable to the spread of the disease than those which existed in the past, and from personal study he was in a position to state that unless measures were taken quickly to combat the evil it would lead to most serious results. Legislation to deal with it had been too long delayed. Nothing had been done except the passing of a Bill to deal with quacks and quack remedies. That Bill had done good, but not as much as it might have done, and quacks and quack remedies were still in existence in some places. Many more treatment centres on the lines of those which had already been set up by the Local Government Board would be needed throughout the country when demobilisation commenced, and time was running very short. The Criminal Law Amendment Bill had been held up, and he assumed that the Joint Select Committee would be discharged, though he hoped that its labours would not be wholly thrown away. He could not understand why the Government had not proceeded with a Bill which was so urgently needed. He pressed that it should be re-introduced and passed into law as quickly as possible. It would be a disgrace to humanity if Clause 5, which made it a crime knowingly to communicate venereal disease, were not enacted. Such an offence might easily be worse than murder, for it might not only wreck one life, but young lives as yet unborn. Regulation 40 D, he believed, would shortly be abolished. He did not think that it had done any real good, but its disappearance left the country without any protection against the wilful spread of the disease. He hoped that a number of points of special importance would be dealt with. First of all it was required that no soldier or sailor should be discharged while in an infected state. He was sorry to say that the total number of infected men was very formidable. Considerable strengthening of the medical provision for dealing with the civil population was also necessary, as the present line of defence against the disease was not sufficient. The Prime Minister had laid great stress the other day upon the vital necessity of raising the standard of public health in the country. He (Lord Sydenham) hoped the Prime Minister realised that the conditions he deplored were largely due to the ravages of venereal disease, that most insidious enemy of the national vigour and the cause of immense economic loss. He pressed the Government to give an undertaking that they would grapple with the peril which would become acute when demobilisation came.

Lord MUIR-MACKENZIE said that the danger regarding the present situation was that it looked like a deadlock. His opinion from his work on the Joint Committee was that prompt measures were required. A disastrously long period of time had been allowed to elapse between the sending of the Bills to the Joint Select Committee. He did hope that the Government would not let the labours of that Committee be thrown away.

Viscount PEEL (replying for the Government) said that the reason why the Criminal Law Amendment Bill had not been proceeded with was the Parliamentary difficulties arising from a crowded session. In judging the future attitude of the Local Government Board towards this subject it was only fair to remember what they had done in the past. Arrangements were made as long ago as April last between the Local Government Board and the Army Council that soldiers about to be discharged should be examined, and that if they were suffering from venereal disease they should be detained in the military hospitals until such time as the disease had disappeared. A fresh situation might arise on demobilisation, but the Local Government Board were fully aware of the dangers which might arise from the release of infected men from the Army and Navy, and at the present moment discussions were taking place with the War Office with a view to preventing infected men being let loose among the civil population. Lord Sydenham might be interested to learn that some 130 treatment centres for venereal disease had already been established in England and Wales. If this was not enough allowance must be made for the shortage of medical staff and other difficulties created by the war. The Local Government Board together with the Ministry of National Service were arranging for the release of army doctors and naval surgeons who had specialised knowledge of venereal disease, and it was intended to press upon local authorities the necessity for establishing further treatment centres and clinics, especially in the evening. He could give a general assurance that the whole matter was being not only examined but dealt with.

The Archbishop of CANTERBURY deplored the delay in dealing with the subject. Several proposals had been made and successively tinkered with, but the matter remained in a state of confusion. He strongly urged that legislative action should be taken to combat the evil at the earliest possible moment.

Lord SYDENHAM thanked the Government for their reply and said that the most important thing, in his opinion, was that there should be coöperation between the Local Government Board and the naval and military authorities.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 13TH.

Influenza in the Army.

Viscount WOLMER asked the Under Secretary for War (1) how many cases of influenza in the British Army in France and England were reported during the months of September and October, 1918; what hospital accommodation was there to cope with these cases; whether any fresh hospital accommodation was provided; and, if so, how many beds; and (2) how many officers and men of the British Army died in England and France respectively from influenza or pneumonia during the months of September and October, 1918.—Mr. MACPHERSON replied: I regret that the figures for the United Kingdom for the month of October are not yet available. The figures for September are:—

	Influenza.		*Pneumonia.*	
	Admissions.	Deaths.	Admissions.	Deaths.
Officers	110	Nil.	20	Nil.
Other ranks ...	2791	18	361	75

I cannot give the figures in the detailed form desired in the case of France. In September there were 92 admissions

to hospital on account of pneumonia and 24 deaths. The figures for October are: 2702 admissions to hospital and 1044 deaths due to pneumonia, and 24,894 admissions to hospital and 421 deaths due to influenza. As regards hospital accommodation on Sept. 1st there were 96,000 vacant beds in hospitals in the United Kingdom, and since that date an additional 8000 beds have been provided.

Viscount WOLMER: Is the right honourable gentleman taking steps to have the mortality statistics of the Army compared with the civilian statistics?—Mr. MACPHERSON: I cannot say whether we are doing that now, but I will see that it is done.

Viscount WOLMER asked whether the right honourable gentleman had received complaints in regard to the overcrowding of hospitals; and whether steps had been taken in all those hospitals in which influenza or pneumonia cases were numerous to reduce the number of inmates.—Mr. MACPHERSON answered: No complaints have been received regarding overcrowding in hospitals. It is impossible in every case to reduce the number of inmates owing to the widespread and very extensive nature of the outbreak, and the fact that the hospitals are at present strained to the utmost by the arrival of wounded from overseas.

Viscount WOLMER asked how many cubic feet of air space per patient was considered necessary by the military authorities for patients in military hospitals suffering from influenza and pneumonia.—Mr. MACPHERSON replied: At present 600 cubic feet of air space has been provided as a minimum in every hospital, and with adequate ventilation and efficient warming there is no evidence that this is insufficient for ordinary cases. It is recognised that cases of influenza and pneumonia require additional air space, and this is given whenever practicable.

Colonel MCCALMONT: Is it not the case that in many districts where there has been this epidemic the figures have been very much lower for the troops than for the civilian population?—Mr. MACPHERSON: That is so.

British Columbia Medical Degrees.

Mr. CECIL HARMSWORTH asked the Colonial Secretary whether he was aware that under existing conditions medical men from British Columbia were prevented from registering in Great Britain unless they took a British degree; whether this was in consequence of arrangements made by the Foreign Office with one or more foreign and Allied countries; and whether any such regulations could be suspended in view of the present great lack of medical men.—Mr. LONG replied: The difficulty in question arises from the fact that it had not been possible to arrange for such reciprocity between the United Kingdom and British Columbia as is considered to be necessary before an Order in Council can be issued applying the second part of the Medical Act, 1886, to that Province.

THURSDAY, NOV. 14TH.

Medical Service of the Air Force.

Mr. JOYNSON-HICKS asked the Under Secretary to the Air Ministry whether he was aware that at the last meeting of the Medical Administrative Committee they unanimously reaffirmed their view that the new medical administrator should be willing to accept the principles laid down in the Medical Advisory Committee's report, on the ground that unless this step were taken all the work of such Committee might be undone to the detriment of the Air Service; and whether the new administrator was prepared to accept such resolution.—Major BAIRD answered: The reply to the first part of the question is in the affirmative. The offer of appointment was made to Colonel Fell on the recommendation of the Medical Administrative Committee, which had not ascertained whether he concurred in the report of the Medical Advisory Committee. One of the conditions of the offer made to Colonel Fell is that he should be guided by the principles laid down by the Watson Cheyne Committee, subject to certain amendments as regards principles of administration.

Rabies in Devon and Cornwall.

Answering Mr. CAREW, Mr. PROTHERO (President of the Board of Agriculture) said: So far there has been no spread of rabies beyond the two counties (Devon and Cornwall) in which it was originally found to exist. But the period of incubation of rabies, though usually one of days, may be one of months, and it is always possible that the disease may have been carried to another part of the country in a dog which has not yet developed it. I trust, however, that the measures which are being taken against the disease in the two counties are such as to insure its final eradication after all the present sources of infection have been brought to light. I am informed by the Local Government Board, who deal with hydrophobia, that there have been no cases of that disease, and consequently no deaths. The number of persons known to the department to have been bitten or scratched by rabid or suspected dogs is 25.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.1.

MEETINGS OF SECTIONS.

Monday, Nov. 25th.

ODONTOLOGY (Hon. Secretaries—F. N. Doubleday, G. Paton Pollitt, J. Howard Mummery): at 8 P.M.

Casual Communication by Mr. J. Howard Mummery.

Papers:

Mr. Cole and Mr. C. H. Bubb: Bone Grafting in Un-united Fractures of the Mandible, with Special Reference to the Pedicled Graft.

The Royal Society of Medicine keeps open house for R.A.M.C. men and M.O.'s of the Dominions and Allies. The principal hospitals in the metropolis admit medical officers to their operations, lectures, &c. Particulars on application to the Secretary at 1, Wimpole-street, London, W.1.

MEDICAL SOCIETY OF LONDON, 11, Chandos-st., Cavendish-sq., W.

MONDAY, Nov. 25th.—8.30 P.M., Paper:—Prof. J. D. Adami, Col., C.A.M.S.: Inheritance and Acquirement of Disease, a Study of the Rejected.

Owing to the declaration of the suspension of hostilities, the meeting of the Society for Monday, Nov. 11th, was adjourned until Monday, Dec 2nd, at 8.30 P.M., when Col. H. J. Waring will open a discussion on Reconstruction in Medical Education and Practice.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY, Nov. 27th.—4.30 P.M., Lord d'Abernon, G.C.M.G. Drink Control in Various Countries.

THURSDAY.—4.30 P.M., Bhupendranath Basu: Some Aspects of Hindu Life.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Clinics each week-day at 2 P.M., Wednesday, Friday, and Saturday also at 10 A.M.

(Details of Post-Graduate Course were given in issue of Nov. 2nd.)

THE THROAT HOSPITAL, Golden-square, W.

MONDAY, Nov. 25th.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

UNIVERSITY COLLEGE, LONDON, Gower Street, W.C.

Two Lectures on Wound Shock.

FRIDAY, Nov. 29th.—5 P.M., Prof. W. M. Bayliss. (Lecture II.)

ROYAL INSTITUTE OF PUBLIC HEALTH, in the Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures on Public Health Problems under War and After-war Conditions (each Lecture will be followed by a Discussion):—

WEDNESDAY, Nov. 27th.—4 P.M., Lecture VIII.:—Alderman C. Spencer: National Kitchens and the National Health.

NATIONAL ASSOCIATION FOR THE PREVENTION OF INFANT MORTALITY, at Dr. William's Library, Gordon-square, W.C.

Three Lectures on the Feeding of Children:—

TUESDAY, Nov. 26th.—5.30 P.M., Lecture III.:—Dr. E. Pritchard: The Drawing up of Diet Sheets.

Vacancies.

Royal Free Hospital, Gray's Inn-road, W.C.—Female Medical and Gynæcological Registrar.
St. Helens, Lancs., Pilkington Special Hospital.—Res. M.O. £500.
St. Peter's Hospital for Stone, &c., Henrietta-st., W.C.—Jun. H.S. £75.
Sheffield, Jessop Hospital for Women.—Hon. Asst. M.O.
Sheffield Royal Infirmary.—Two H.S.'s. £150.
Shrewsbury Dispensary, 42, St. John's-hill, Shrewsbury.—Locum M.O.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Biggar (Lanark), Pontymister (Monmouth), and Witney (Oxford).

Births, Marriages, and Deaths.

BIRTHS.

DUTTON.—On Nov. 16th, at St. Petersburgh-place, Bayswater, the wife of Surgeon Lieutenant F. B. Dutton, M.B., R.M., of a daughter.

MITCHELL.—On Nov. 16th, at Leintwardine, the wife of Major Wright Mitchell, R.A.M.C., of a daughter.

QUACKENBOS.—On Nov. 20th, at a nursing home in Taunton, the wife of Maxwell Quackenbos, M.D., of a son.

MARRIAGES.

ALLEN-MAUGER.—On Nov. 12th, at Rouen, T. Stevens Allen, F.R.C.S. Ed., Captain, R.A.M.C., son of Mr. and Mrs. T. Stevens Allen, of "Tenchleys," Forest Hill, to Elisabeth, daughter of the late Mons. G. L. Mauger and Mme. Georges Mauger, of Rouen.

WILTSHIRE—MONCK-MASON.—On Oct. 26th, at Alexandria, Captain H. G. Wiltshire, R.A.M.C., to Eileen, daughter of the late Colonel G. G. Monck-Mason, R.A., and Mrs. Monck-Mason, of St. Jean de Luz.

DEATHS.

COCKE.—On Nov. 16th, at Wimpole-street, W., of disease contracted on active service, Robert Sturgeon Cocke, F.R.C.S., Captain, R.A.M.C., aged 44.

JONES.—On Sept. 30th, killed in action, Captain Evan Lawrence Jones, R.A.M.C., attached 2nd H.L.I., aged 30.

JUKES.—On Oct. 18th, in Egypt, of neuritis and heart failure after rheumatic fever, Captain Andrew Monro Jukes, M.D., I.M.S.

PHILSON.—On Nov. 13th, at Karachi, India, Colonel S. C. Philson, A.D.M.S., R.A.M.C., aged 58.

SPURRELL.—On Nov. 8th, at the 19th General Hospital, Alexandria, Captain Herbert George Flaxman Spurrell, R.A.M.C., aged 41.

WINTER.—On Nov. 15th, at the 20th General Hospital, France, Captain Laurence Amos Winter, M.D., R.A.M.C., aged 50.

WOO.—On Nov. 15th, at South Devon and East Cornwall Hospital, Frederick Joseph Woo, M.B., Ch.B., F.R.C.S. Edin., aged 27, House Surgeon of the Hospital, from pneumonia following influenza.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

EDITORIAL NOTICE.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Communications, Letters, &c., to the Editor have been received from—

A.—Dr. W. Allingham, Orsett; Admiralty, Lords Commissioners of the, Lond.; Dr. F. W. Alexander, Lond.

Notes, Short Comments, and Answers to Correspondents.

THE TUBERCULOUS SOLDIER.

Dr. Jane Walker, at the Royal Institute of Public Health on Nov. 13th, described the problem of the tuberculous soldier as one of the most pressing before the country. Owing to the lowered standard of health demanded from recruits in the later days of the war many conscripted men were, she said, unfitted for the duties imposed upon them, and as a consequence became broken in health. More especially had this been the case with the tuberculous. The medical profession, Dr. Walker continued, were not in the best position to deal effectively with tuberculosis, since what Sir George Newman had described as "the when? the how? the what? and the why?" of treatment had not formed part of the training of the medical student, who received practically no instruction at all in prognosis. The omission to instruct medical students in the beginnings of disease was specially disastrous in the case of tubercle. The average case which the student saw in hospital was so advanced that even the man in the street could recognise it as tuberculous, but even these cases were seen in small numbers, as they were not admitted to the wards of general hospitals. Was it therefore to be wondered at, the lecturer queried, that so many practitioners failed to recognise early tuberculosis? While, on the one hand, this failure to recognise early cases had led to the admission of advanced cases to the Army, on the other hand many men had received exemption, as the result of X ray shadows, who were quite normal. Dr. Walker described the failure of sanatorium benefit under the National Insurance Act as scandalous. In London large numbers of patients were waiting for treatment, beds were few, and the period of treatment granted to each patient had been reduced to six weeks, a time totally inadequate to deal with the disease. Naturally, under such circumstances, sanatorium treatment was a failure. The time to deal with the tuberculous soldier was in peace. In the lecturer's experience the relaxation of military discipline resulted in the ex-soldier running amok for a time and taking no interest in work. This constituted a great difficulty in the after-care of the tuberculous soldier. Much of the value of sanatorium treatment was thrown away by allowing the patient to return home without supervision and without occupation. At Nayland Sanatorium a school had been set up for instruction in sheet-metal work and silver jewelry making. These trades had been selected to fulfil three conditions: (1) the tuberculous workman to be his own master; (2) not to work against time; and (3) to obtain an income sufficient to keep him. The man was instructed how to keep a village shop, and was taught clock and watch cleaning as a fill-up for his time. The discussion which followed the lecture centred round the desirability of life in the Dominions, especially South Africa, for the tuberculous soldiers, provided that they were welcome guests, and the necessity of preventing by legislation the production of new slums to take the place of those that had been swept away.

PUBLIC HEALTH IN BOMBAY.

SEVERAL circumstances have combined to render the health conditions of Bombay abnormal during the past three years, chiefly on account of the war. There has been an increase in the population owing to high wages and abundant employment; increase in the birth-rate and in the mortality; overcrowding in every direction; increase in rents and food prices; lastly, increase in income for most of the labouring classes, as well as for the richer people engaged in commerce, while for the salaried and official classes and for persons of small fixed incomes there was a virtual reduction owing to taxation and increased cost of living. The enormous traffic through this city by sea and land, particularly in connexion with the war, adds to the labour and difficulty of health administration, and a special assistant health officer was appointed, and the conservancy staff strengthened, on the suggestion of the chief medical officer, Dr. J. A. Turner.

The health conditions of the city, as set out in Dr. Turner's report for 1917, taking everything into consideration, compare favourably with the normal before the war. Calculated on a population of 979,445 (that of the census of 1911), the total death-rate was 34·09 per 1000, but Dr. Turner considers the population to have really numbered over 1,100,000. There was no epidemic of any disease except plague, and that only to a small extent. The causes of the infant mortality (304 per 1000 births) are considered at length: respiratory diseases, debility, and convulsions account for four-fifths of the whole. Much good work has been done

by Lady Willingdon's organisation for securing proper treatment for women during confinement and for their infants after birth. There are 12 lady health visitors to supplement the work of the corporation midwives, as well as three maternity homes with an infant milk depôt for each. The death-rate in Bombay from all causes (34·09 per 1000) in 1917 was in excess of that for the preceding year (31·21), but slightly below the decennial average (1907–16) of 34·59. The highest ratio was that for respiratory diseases (11·46 per 1000), showing considerable increase over the decennial average of 8·81; nervous diseases (2·10) were also slightly in excess of the average (2·01), but in all other important affections there was a decrease in mortality. The cholera ratio was 0·06, compared with 0·38; that for plague was 1·74, compared with 3·52; and that for small-pox 0·27, compared with 0·59. Zymotic diseases generally showed a ratio of 6·03, compared with 9·22 for the decennium, a very noticeable improvement. The death-rate from all causes varies very considerably according to caste or race. For Hindus, who constitute the large majority of the population, the ratio was 34·46; for Mussulmans, 38·31; for Parsees, 19·81; for Europeans, 21·85 per 1000.

Plague has been continuously present in Bombay since 1896—that is, for 21 years. In 1903 it caused 20,788 deaths, or 26·78 per 1000 of the population; in 1915 there were only 599 deaths (0·61 per 1000), in 1916 the ratio was 2·02, and in 1917 there were 1706 deaths (1·74 per 1000). There were attacks and deaths in each month throughout the year 1917, and from March to the beginning of June it was epidemic, being worst in April as usual. The two Colaba wards suffered most (6·25 and 5·78 deaths per 1000). Inoculation and rat destruction were carried out vigorously; 501,632 rats were examined at the Parel Laboratory, of which 2·22 per cent. were found to be infected. In April the percentage infected was 5·1. Wherever a plague case occurred, or an infected rat was found, the place was disinfected throughout with posterine, as well as all neighbouring gullies and passages. The total cost of disinfectants used was 29,900 rupees.

Cholera prevailed slightly throughout the year, there being 74 cases and 61 deaths, but did not become epidemic at any time. The death-rate was 0·06 per 1000, compared with a decennial average of 0·38.

Tuberculosis.—The mortality from tuberculosis, 2·16 per 1000, was higher than in any of the three years immediately preceding, but lower than the decennial average (1907–16), which was 2·58. The apparent increase over the years 1914 to 1916 is considered to have been due to increased accuracy in diagnosis, many cases that would formerly have been returned as fever or bronchitis being now correctly diagnosed and returned as tuberculosis. Moreover, the facilities provided by the tuberculosis dispensaries for advice and treatment have brought to light many cases that would otherwise have been undetected. Fort, Southern Section, had the apparently enormous tuberculosis death-rate of 14·44 per 1000, but of 50 deaths from this cause 43 occurred in the Lady Hardinge Hospital, leaving only 7 deaths (2·02 per 1000) to be debited to the section. The Anti-Tuberculosis League provides two dispensaries, each with a medical officer and three nurses. All cases are reported to the health officer and disinfection of the homes is carried out. A sanitarium is about to be established by the league for treating early cases, segregating advanced cases, dealing with glandular tuberculosis in children, and to be utilised as an open-air school.

Enteric fever.—A considerable increase in enteric fever occurred among the civil population in 1917, commencing in June; during this month and the three months following there were 189 cases and 96 deaths. The cause or causes could not be discovered with certainty. Abolition of the open system of drainage, of the basket privy, and of the night-soil depôt is recommended, and increase in facilities for removal of house refuse and accumulations of manure, so as to diminish breeding places of house-flies, and, perhaps most important of all, early notification.

This most interesting report is accompanied by valuable appendixes of statistical data and is illustrated by many admirable diagrams. If a plan of Bombay could also be inserted we feel sure that it would be appreciated by students of public health and municipal administration.

THE TALE OF A CONVOY.

Sir John Bland-Sutton had the good fortune to travel with a convoy made up of many and various ships, and as he travelled in the escorting cruiser he learned to understand the difficulties over which the British Navy has had to triumph in shepherding its awkward but willing flocks across the Atlantic and into safety. The text of his story, entitled "The Tale of a Convoy" (London: Adlard and Son, pp. 39), is Mr. Kipling's cry of the big steamers:—

> "Send out your big warships to watch your big waters,
> That no one may stop us from bringing you food.
> . . . . . .
> For if anyone hinders our coming you'll starve."

The instinct of a naval captain is to make his ship do precisely what the other ships in the fleet are doing, so keeping her relatively to the other ships always in the same spot. The merchant captain is ever an individualist, and his ship generally gives him little help when he tries to sail her in a fleet. She goes her own gait steadily, she only with difficulty accommodates her course to that of others. But use becomes second nature, and the captains became quite good at station-keeping in the fortnight they spent together, with the escorting cruiser every now and then sailing rings round them and making caustic signals to the laggards and wanderers. Sir John Bland-Sutton recognises the alert devotion to their multifarious duties given by all the officers and men of the big cruiser, the readiness with which they turn out in alarms, the zeal with which a destroyer rushes out to protect one of its charges, the variety of the methods of attack prepared for meeting submarines. In fact, the landsman who reads this little pamphlet does well, for he will learn from it to realise how many are the professions included amongst the personnel of a ship of war.

The author does not forget to emphasise an appeal that has often been made in THE LANCET. "Great ingenuity is exercised to increase the carrying capacity of cargo ships and enable the owners to become richer, but little consideration is given to make the quarters for sailors, firemen, and stewards comfortable." Surely at the end of this war the country, mindful of the splendid help it has had from these devoted seafaring men, will see to it that they are at least as well protected as their brethren who work in factories. No one who reads this little book and its stories of the sufferings endured by the sea-folk in the war can ever but be grateful to them for the invaluable help they have doggedly gone on giving to the country, above all, perhaps, the engineers. The book is written in a pleasant style, which makes the pictures live before us, and even if the account of the Thibetan hell in the last chapter makes us shiver—well, that was intended. Sir John Bland-Sutton is to be congratulated on the interest of the story he had to tell and on the skill of his narration.

THE CHILDREN'S JEWEL FUND.

To the Editor of THE LANCET.

SIR,—The Administrative Committee of the Children's Jewel Fund (a subcommittee of the National Baby Week Council) is anxious to make the best possible distribution of the money which has so far been collected or raised by the sale of jewels by the Appeal Committee. Grants are available for the inception of new infant welfare centres and day nurseries, or towards certain new developments in connexion with existing institutions of the same kind. To the committees of voluntary institutions grants up to 50 per cent. may be given, while the committee is willing to consider applications for small grants towards the initial equipment of entirely municipal undertakings. Grants amounting to £5099 3*s.* have already been allocated to London, whilst Greater London and the Provinces have received £5015 5*s.*

Full information may be had on application to the Secretary to the Administrative Committee, 27A, Cavendish-square, W. 1. Jewels and money should be sent to me at the offices of the Appeal Committee, 175, New Bond-street, W.1.

I am, Sir, yours faithfully,

CONSUELO MARLBOROUGH,
Honorary Treasurer, Administrative Committee
of the Children's Jewel Fund.

Nov. 16th, 1918.

PRECAUTIONS AGAINST FIRE.

WE have often called attention to the warnings issued by the British Fire Prevention Committee in regard to the accidental occurrence of fires at celebrations and entertainments. The approach of the festive season, which the happy issue of the war is likely to make more festive, makes their repetition desirable. The general precautions suggested are:—

Flags and bunting.—All kinds of bunting should be kept well clear of open lights and fires, and away from electric switch-boards and fuses.

Evergreens.—All dry shrubs are easily ignited, especially the fir-trees used in the winter, as they contain a considerable quantity of resin.

Celluloid, being a highly inflammable material, should not be used in decorative schemes.

Tissue paper (unless properly treated) should not be used as a decoration or covering for illuminated globes.

Paper lanterns.—All paper and similar lanterns should be hung by wire, and during the period they are lighted should be watched to see they do not swing. A swinging "Chinese lantern" easily catches fire.

Candles are easily bent out of shape, even by the slight heat of another light below. Bent candles drop down and set things alight. If used for window illumination, curtains, &c., must be well tied back and raised blinds securely fastened.

Electric wiring.—Do not make the slightest change in electric wiring without consulting a competent electrician or an electrical inspector.

With additional Christmas precautions as follows:—

Christmas trees should not be placed near window curtains or in positions in which a draught may cause inflammable draperies, &c., to be blown on to the lights.

Cotton-wool (unless properly treated) should not be used to represent snow, as it is highly inflammable. Asbestos fibre or slag wool are good substitutes.

Matches should not be put within the reach of children. Children should not be allowed to light Christmas tree or other candles unless adults are present. They frequently set fire to their clothing instead.

Buckets of water should always be available, also buckets or bins of dry sand with scoops where oil or spirit is used. Stout blankets are useful for smothering incipient fires. Copies of this warning (No. 33) may be obtained gratuitously on written application, enclosing postage, to the Committee at 8, Waterloo-place, Pall Mall, London, S.W.1.

Wullie.—The medical practitioner in question would regard the humorous criticism as a deeply-thought-out insult.

A Triple Plea

FOR A MORE RIGOROUS STANDARD OF CURE IN THE TREATMENT OF GONORRHŒA.

BY E. R. TOWNLEY CLARKSON, M.A., M.R.C.S., L.R.C.P.,

SENIOR CLINICAL ASSISTANT, MALE GONORRHŒAL SECTION OF THE GENITO-URINARY DEPARTMENT, LONDON HOSPITAL; HONORARY MEDICAL SECRETARY, NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES; ADDITIONAL DEMONSTRATOR OF HUMAN ANATOMY, UNIVERSITY OF CAMBRIDGE.

With a

SUGGESTED SCHEME AS REGARDS TESTING FOR CURE IN GONORRHŒA,

BY A. MALCOLM SIMPSON, B.A., M.B., D.P.H. CANTAB.,

SURGEON, OUT-PATIENTS, ST. PAUL'S HOSPITAL; SENIOR CLINICAL ASSISTANT, GENITO-URINARY DEPARTMENT (WOMEN), LONDON HOSPITAL.

AND

E. R. TOWNLEY CLARKSON.

INTRODUCTION.

AN increase of venereal disease (V.D.) was formerly one of the aftermaths of war. "Post bellum Venus venit." This statement now requires some qualification. Gonorrhœa and her grim sister syphilis are even now striding throughout the land, and I believe with increasing vigour, while the battle still rages.[1]

A further increase in the victims of Venus when peace is declared is inevitable. The emotional condition of the nation will be intensely susceptible to various stimuli, and correlated to this there will be a widespread outburst of promiscuous sexual activity, with much resultant venereal disease. The pathological aggregate will be further augmented by the influx into this country of thousands of men and women, many of whom will be suffering from these disorders in a chronic and, in their estimation, in a non-infectious condition. Here is a menace to the national health the immensity of which cannot be realised. The number of such cases no man can forecast, but of necessity it will be great.

It is obvious that many practitioners will be called upon in the immediate future to treat V.D. to whose purview in the past such cases have never or only rarely been presented. Upon such will rest a great responsibility—the responsibility of deciding whether patients suffering from V.D. are in a condition to assume or resume conjugal relations. Upon their dicta will also hang the fate of thousands of other men and women. If their verdicts be carelessly passed large numbers of the unmarried, fallaciously encouraged by the verdict of "cured," will pass from consulting-rooms and clinics as disseminators of the disease of which they believed themselves to be cured. The responsibility applies in cases of syphilis and gonorrhœa, but I am more immediately concerned with the question of the latter. For reasons I need not enunciate, I am convinced that the national health will be endangered to a far greater extent by the latter rather than by the former.

To treat imperfectly or to discharge prematurely a patient suffering from pneumonia may imperil his health and possibly cause his death. Similar neglect with regard to a case of venereal disease *must* imperil the health and may cause the death of many individuals.

Apart from the purely human factor reference should be made to the great economic saving which the nation would achieve if every case of gonorrhœa was searchingly tested before being "discharged as cured." Not only would the expense incurred by the community for further treatment, involved by the recrudescence of the disease after the pseudo-cure had taken place, be saved, but many thousands of new cases infected by the imperfectly cured would never ensue and the cost of their treatment would thus be obviated. If the reduction in efficiency of these individuals were taken into account in terms of work-days lost, it would be realised how great a national gain would thus be achieved.

[1] This was written before the cessation of hostilities.

In the past (a very recent past) the task of examining a patient suffering from gonorrhœa before discharging him as cured generally fell upon the medical man who had treated the case. To-day his responsibility is a great one, but one which is more easily discharged. It is in many cases a comparatively simple matter to send the patient to a Local Government Board clinic with a request for a thorough examination to be made as to whether he is cured. Such a test should be carried out at least on two separate occasions, after a due cessation of treatment.

It is true there are still towns and large country areas without a clinic. It is impossible to over-estimate the crass lack of prevision on the part of the responsible municipal or other authorities who thus fail to make provision for the reduction of suffering and disease among their fellow-creatures.

It is impossible to conceive of any adequate explanation; it is equally impossible to think that public opinion will allow national health thus to continue to be menaced by such factors as pseudo-religion or meticulous municipal and other jealousies, which thus stand in the way of normal hygienic development.

Venereal disease has been a sociological problem; it is now becoming a biological factor. In passing, I would quote from Norris:—

"There is probably no other disease known to medical science that has caused as much suffering and sorrow throughout the civilised world as has gonorrhœa. Neisser states that, with the exception of measles, gonorrhœa is the most widespread of all diseases. It is the most potent factor in the production of 'race suicide,' and, by sterilisation and abortion, does more to depopulate the country than does any other one cause. The number of deaths annually that can be traced directly to this disease is difficult to estimate, but it is undoubtedly large. The majority of deaths due to this disease are usually under other headings in mortality statistics." (Norris on "Gonorrhœa in Women.")

These words are as a trumpet-call to efficiency of treatment. It is in the atmosphere they conjure up that I venture to submit the following fundamental principles for consideration in relation to a disease which is essentially a curable and almost entirely a preventable one.

I. ON THE NECESSITY OF EXERCISING THE MOST RIGOROUS STANDARD OF CURE.

It is but the enunciation of a platitude to state that the standard of test for cure is a variable one. The verdict of cured is given at times solely on the grounds that there is no discharge (with or without a macroscopic examination of the urine). Between this the lowest rung of the ladder of tests and the highest in the shape of the scientific and relatively exhaustive "marriage tests" there are many intermediate steps.

In gonorrhœa the most rigorous test possible should be utilised. If such a test was always insisted upon the verdict "cured" would not result in the tragedies which too often follow in its train.

The appreciation of the abstract is sometimes more easily realised by a statement of the concrete. With a view to pressing home an insistent plea for the universal application of a higher standard of cure, I will deal with a case which may be regarded as typical of a lamentably large group of patients. A man who is suffering from gonorrhœa is put through a certain course of treatment. As a result the disease is apparently cured, inasmuch as the standard of cure set up by his medical attendant has been attained. In the course of time—and here it is most important to point out that the intervening time may be one of months or of years—the man marries. Between his "cure" and marriage there has been no exposure to a fresh infection. Shortly after marriage he discovers that he is suffering from the old complaint. Now comes the tragedy. He is forced to arrive at a conclusion which he would give all he possesses to forgo. What are his data? He was told that he had been cured of his previous attack, he knows he has been leading an absolutely chaste life. He is now suffering from the same disease. The only conclusion to which he can come (with his limitation of knowledge) is that his wife has lapsed from the paths of virtue and, having contracted the disease herself, has now handed it on to him. Here we see the elements in an inexpressibly sad and terrible domestic drama, all too frequently enacted. The man

forced by apparently irrefutable reasoning to the above conclusion, the wife convinced of her own integrity, no mediator to explain and heal the breach. Apart from pathological results, there follows either a life-long separation with all its attendant temptations and disabilities, or a continuation of a so-called union, which, beginning with a lack of faith and continued in an atmosphere of mutual recrimination, must almost necessarily result in a permanent wreckage of happiness. What is the explanation? It is as simple as it is tragic.

The standard of cure which was originally set up and which had been attained was a superficial one, and therefore imperfect one. The examination on which the verdict of "cured" was based was insufficiently searching to discover the inimical gonococci. In one or both of the vesiculæ seminales these had lingered in apparent quiescence during the months and possibly during the years, only then to break out from their lurking place with renewed virulence on the consummation of marriage. The husband's bridal gift to his wife was, indeed, a terrible one, and the infection which she derived she has handed back (in some cases with interest) to her all unconscious spouse. If at the time of "cure" the contents of the vesicles had been expressed and examined the danger would have been detected and eventually all would have been well.

I need but merely refer to pyosalpinx, sterility, gonococcal rheumatism, and chronic invalidism as other lesions which may accrue from the non-insistence upon the most rigorous test as to cure. It is stated that whereas syphilis constitutes a third of pathology, gonorrhœa is a causal factor in nearly half the total number of cases suffering from diseases peculiar to women. It is surely unnecessary, in the light of such a statement, to debate upon the grave responsibility which presses upon all of us to find out the most stringent standard of cure known to science, and, finding it, to use it.

For information as to the nature of such a standard of cure I must refer my readers to the suggested scheme at the end of this article.

II. The Most Rigorous Standard of Cure Must be Applied to Every Type of Gonococcal Disease.

There is no doubt that an insistence upon utilising the highest standard of cure does obtain amongst certain members of the profession. It is, however, a remarkable fact that a certain proportion of these penultimists fail to carry out their practice to a logical conclusion. These practitioners insist that before a married patient be allowed to resume marital relationship, or a bachelor on the verge be permitted to contract marriage, he should be run through the gamut of urinary, urethral, prostatic, and vesicular examinations.

But what of the bachelor who determines as such to remain? And here is my point: in nearly every instance he is discharged as "cured" after an essentially less stringent test than is insisted upon by our idealists when dealing with the husband actual or potential. Why is the married man or matrimonial candidate so rigorously overhauled? Because he may infect his wife that is or is to be. It is, indeed, a terrible fate for a married woman to develop a pyosalpinx as the result of an infection contracted from her husband. It is surely more terrible if many women contract the same hideous complaint, for without cynicism one must admit that in many instances such will be the result of prematurely discharging as "cured" the amorously flitting bachelor. Whether the suffering woman be a matron of virtue or the mistress of many is possibly beside the point—from the logical purview; from the sociological the latter is undoubtedly the more serious.

A rigorous test is imperative for the married man in order to protect his wife; for the bachelor it is necessary in order to safeguard society. I submit that in every case of gonorrhœa the most rigorous test known should be applied irrespective of the patient's actual or potential matrimonial position and irrespective of the apparent lightness or severity of the disease. If this is not carried out the apparently cured will act as venereal emissaries in the dissemination of disease.

Let us remember that, in urging the necessity of the ideal standard of cure, we are not only making for the reduction of suffering and the prevention of domestic tragedies, but we are working for the repopulation of England. By the prevention of gonorrhœa we prevent a large proportion of that sterility by which countless women are robbed of their potential offspring, and England of innumerable citizens, at a time when we shall need them most.

III. The Standard of Cure should be Systematically Employed.

Amidst the multifarious activities and tensions thrust upon us we have not fully realised the value of the admirable machinery set up by the Local Government Board in the shape of venereal cliniques. I believe that history will show the initiation of such a scheme to be one of the greatest pieces of public health work ever originated.

As a result of this organisation a far-reaching series of statistics, medical and sociological, should be at our disposal. But unless a uniform standard of cure be systematically used the data from various institutions would not be comparable, and it would be impossible to appraise scientifically the value of the various methods of treatment employed. Moreover, a fallacious index of the efficiency of different institutions will originate—for the clinique with a low standard of cure will have many cures to its credit, whilst the one with an ideally stringent standard will have but few. We have blindly worshipped too long and will continue to worship at the shrine of numbers—let us make certain that our numerical basis be a sure one.

Let it not be thought that by suggesting that any particular "standard of cure" should obtain in all clinics I am advocating a policy which might result in a stereotyped conservatism. The standards of to-day are unfortunately in many cases the standards of yesterday, but there is no reason why those of to-morrow should be identical with those of to-day.

Let us, however, be certain that the standard of to-day be the most rigorous one possible. It is easy to assent to such a statement, but difficult to secure that any given standard is the most perfect. The underlying fundamental principle of such a test is that every weapon in the antigonococcal armoury should be utilised in order to dislodge that inimical micro-organism from every conceivable lurking place. From this it follows that every possible lair of a glandular nature should be most thoroughly explored by a searching examination of its expressed secretion.

How are the various standards to be compared? I would tentatively suggest that in one group of clinics a certain standard of cure should be employed, whilst in another group another standard should be initiated. Care should be taken that the nature of the cases and the treatment administered should be as similar as possible. After a given period the number of cases which had been discharged as cured and which had returned for further treatment (a new infection being eliminated) should be compared. The comparison instituted therefrom should give evidence with a fair amount of scientific verity of the validity of the varying standards employed in the two groups of cliniques. In the case of large cliniques such an experimental method could be utilised with still greater advantage.

I fully realise the difficulties which exist in these times of levelling up standards in medicine as in other spheres, but in this instance there is a peculiar necessity, eugenic and economic, incident to the present condition of affairs, which calls for the exercise of every possible endeavour in this direction.

In these days of ubiquitous venery it is for us to know how, and knowing how, to act in such a way as to cripple, if not eventually to destroy, the luxuriant and deadly growth of this particular upas tree in the forest of disease.

SUGGESTED SCHEME AS REGARDS TESTING FOR CURE IN GONORRHŒA.

By Malcolm Simpson and E. R. Townley Clarkson.

In the interest of the public health it is imperative that the most stringent standard of cure should be employed before a patient who has suffered from gonorrhœa is "discharged as cured." If such a practice does not obtain many patients will be set at liberty with a fallacious sense of security. In this way venereal clinics and practitioners will be acting as distributing agencies of disease.

We venture to suggest below a course of procedure to be followed before a patient is discharged. The method is

necessarily a tentative one. It is one which is used in the course of our hospital and private practice. We are aware that many may regard it as unnecessarily rigorous. We hope that with the lapse of time and the ingress of new ideas it may be improved by the introduction of more searching methods, but we must state our belief that the adoption of any standard of a less rigorous nature would be fraught with great individual and therefore sociological dangers.

I. *Males.*

1. Suspend treatment for at least one week. Patient should be advised to take alcohol as a provocative stimulant. If for any reason this should be considered inadvisable, the alcohol may be administered as a non-recognisable constituent of some palatable mixture.

2. Patient to present himself for examination, having if possible refrained from micturition all night, or, at least, from four to six hours. Meatus examined and urethra "milked up" from bulb. The bacteriologist takes meatal drop on platinum loop, film is made, culture-tube is then inoculated. If no meatal drop then platinum loop is to be passed into urethra, and mucous membrane stroked forward, and film made and tube inoculated from wire. Patient micturates first portion of urine into sterilised vessel, which bacteriologist examines in culture media. Centrifugalisation to be carried out or not as seems desirable. Any threads or deposit examined in film and culture. Glans penis is cleansed with soap, and later on with sterilised water, foreskin retracted, and urethra washed out with sterilised water, and patient placed in knee-elbow position; the glans penis is not to be touched; shake out last drop of fluid in urethra. Systematically palpate prostate and vesicles, special attention to be made to any feeling of abnormality—e.g., thickened or occluded vesicles or nodules in prostate. Massage prostate and vesicles till a drop appears at meatus or presents itself after milking urethra forward from the bulb.

N.B.—The drop may be either like white of egg—i.e., slightly opalescent and homogeneous—or in marked cases turbid, yellow, or granular.

Films are then made of the prostatic and vesicular fluid and culture-tubes inoculated.

The glycerine drop is a product of the anterior urethra, and indicates that the prostatic or vesicular secretion has not presented itself at the meatus.

Finally, a urethral examination should be made, preferably by Wyndham Powell's instrument with magnifying eye-piece. The instrument having been passed, the anterior urethra from the bulb forwards is carefully examined in order to ascertain its condition as regards (*a*) hard or soft strictures or infiltrations; (*b*) intra-urethral warts; (*c*) infected follicles; (*d*) any abnormal congenital condition, e.g., angiomata. At the same time the roof and the floor should be carefully palpated over the urethroscope tube in order that any peri-urethral infiltrations present may be discovered.

The glans penis is to be examined for para-urethral follicles, especially in the cases of patients exhibiting a hypospadiac or epispadiac condition. The perineum should be examined with a view to discovering the presence of cowperitis and perineal abscess, &c.

II. *Females.*

Suspend treatment for at least one week. Patient should be advised to take alcohol as a provocative stimulant. If for any reason this should be considered undesirable the alcohol may be administered as a non-recognisable constituent of some palatable mixture. Examine as soon after menstrual period as possible. It is advisable to always wear gloves during examination of females. An abdominal examination should be made with the object of noting any abnormality. The patient should be examined in the dorsal position, leaning back in a urological chair, with the thighs flexed on abdomen and knees supported in crutches. The examiner wears a suitable head lamp.

Method of Examination.

1. Remark presence or absence of discharge, and, if any, note quantity, consistency, and colour.

2. *Vulva.*—Vulva is to be cleansed and Bartholin's glands to be carefully examined; note specially redness around opening of same—squeeze out contents if possible; resultant fluid to be placed by bacteriologist on film or culture-tube.

3. *Urethra.*—The meatus is to be examined for the presence of pus. The floor should be pressed forward by finger in vagina and film should be made and culture-tube inoculated with the secretion expressed. If no drop expressed, platinum wire passed into urethra, and mucous membrane stroked forward, slides should be made and tubes inoculated from wire. Crypts in vestibule around meatus urinarius should be carefully looked for and notice taken as to infection. Small retractor speculum should be introduced and the urethra examined thereby, especially as regards infected Skene's tubules. Patient micturates; culture-tubes to be inoculated; centrifugalisation if deemed necessary.

4. *Vagina.*—A speculum, preferably Cusco's or Ferguson's, is to be introduced and an examination made of the vagina. The cervix is to be exposed and any pathological appearance, such as erosion, polypi, cysts, or ulcer, noticed. If secretion (either the normal ropy mucous secretion or pus) issues from the cervical canal a film is to be made and a culture-tube inoculated. If none is seen, then gentle pressure should be made by means of a blunt sponge-holder forceps in an antero-posterior position so that the contents of the deeper cervical glands may be expressed. A film should be made and a culture-tube inoculated with any secretion so obtained.

5. A bi-manual examination of the uterus and adnexa should be made, so that evidence of any disease may be noted.

The above should be carried out on two occasions at intervals of a month.

Note.—It is advisable that the bacteriologist should be present himself and take his own specimens.

No mention has been made of the place of provocative vaccines and the complement-fixation test in connexion with testing for the presence of gonococci. We realise the potentialities associated with these methods, but we do not at present regard their efficacy as sufficiently proved to justify their inclusion in a routine scheme.

We take this opportunity of thanking Dr. G. T. Western and Dr. P. N. Panton, of the London Hospital, for their advice as to the bacteriological points involved in the foregoing scheme.

A NOTE ON

THE USE OF "ANTIGENS" IN DIAGNOSIS BY THE WASSERMANN REACTION:

THE NECESSITY FOR FURTHER INVESTIGATION.*

BY C. H. BROWNING, M.D. GLASG., D.P.H. OXON.,
DIRECTOR, BLAND-SUTTON INSTITUTE, MIDDLESEX HOSPITAL;
AND
E. L. KENNAWAY, M.D. OXON., D.SC. LOND.,
CHEMICAL PATHOLOGIST, BLAND-SUTTON INSTITUTE, MIDDLESEX HOSPITAL.
(*From the Bland-Sutton Institute of Pathology of the Middlesex Hospital.*)

THERE can be no doubt that the adoption of a "standard" antigen would introduce a valuable simplification into the performance of the Wassermann reaction. It is the object of the present note, however, to draw attention to limitations of antigens in common use, which should preclude the adoption of any single one as a standard.

The property which a substance or a mixture must possess in order to be termed a syphilitic antigen is that when mixed with syphilitic serum (heated at 56° C.) in suitable proportion and added to fresh guinea-pig's serum it deprives the latter of its hæmolytic or complementing power; a necessary corollary is that the same amount of "antigen" along with non-syphilitic serum shall be, in comparison, practically devoid of this action on complement.

Stages in Evolution of Syphilitic Antigens.

The following stages may be traced in the evolution of knowledge as to the syphilitic antigen:—

(1) The demonstration that a watery saline extract of certain congenital syphilitic livers possessed this property (Wassermann, Neisser, and Bruck), which has subsequently been found to depend on autolysis rather than on the presence of abundant spirochætes.

(2) The proof that alcoholic extracts of normal tissues also yielded a syphilitic antigen (Levaditi and Yamanouchi, Porges and Meier, &c.). As commonly used, such extracts contain alcohol, which is by no means a negligible factor in the production of the antigenic effect.

(3) The demonstration that the property resides to a considerable extent in the ether-soluble, acetone-insoluble fraction of such alcoholic extracts (Noguchi), even granting that, as McLean states, the antigen is not "lecithin," but something which is precipitated along with it.

(4) The observation (Browning, Cruickshank, and Mackenzie [4]) as to the enhancement of antigenic power conferred on such lipoid mixtures by the addition of cholesterol; also the evidence subsequently afforded that crude alcoholic extracts could be enhanced in a similar fashion (Sachs).

* A Report to the Medical Research Committee.

The question as to which is the "*best*" antigen has received attention since an early period of such investigations. For practical purposes it is desirable that the quantitative difference between a negative and a positive serum, as measured by the excess of the amount of complement which the serum-antigen mixture will inactivate in the latter as compared with the former case, should be as great as possible, since this is the only index of positiveness which exists. Accordingly, extracts of a variety of more or less normal organs have been examined and it has been found in general that alcoholic heart extracts possess this property to an outstanding degree; thus human heart extract has been recommended by Michaelis and has been employed as syphilitic antigen for routine purposes by Thomsen and Boas,[1] and a similar extract, with the addition of cholesterol, has been recommended by Fildes and McIntosh,[5 7] who are supported by Walker and Swift.[9]

Browning, Cruickshank, and Gilmour,[3] in their examination of the ether-soluble, acetone-insoluble fractions of various animal tissues, found that the heart "lipoids" (from the ox) constituted a more potent antigen than similar products derived from ox-liver and kidney and egg-yolk, but they observed that ox-heart lipoid plus cholesterol, when mixed with certain normal sera (one being that of a laboratory worker who habitually used his own serum as negative control), led to a very great inactivation of complement, which was not attended by a particularly high anticomplementary property of the lipoid mixture by itself. Thus they did not feel justified in adopting it for purposes of diagnosis. They therefore continued to use liver lipoid in the full knowledge that the liver-lecithin plus cholesterol, as compared with certain other antigens, caused less complement fixation along with most syphilitic sera.[3] This deficiency was, however, considered to be compensated for, to a great extent, by the fact that when using the liver lipoid in parallel series with lipoid plus cholesterol, if a serum caused more complement to be inactivated in the cholesterol series than in the series without cholesterol, this was an indication of its syphilitic character and could be utilised in the diagnosis of weakly reacting sera.

Heart Extract plus Cholesterol Antigen.

The tendency of crude heart extracts plus cholesterol to cause a considerable amount of complement fixation with non-syphilitic sera has been recorded by a number of observers, especially in America (e.g., Bronfenbrenner and Schlesinger,[2] Smith and McNeal[8]). On the other hand, the use of such an antigen, as first advocated by McIntosh and Fildes, has found much favour and neither these workers nor certain others have found non-specific effects, which doubtless depends on the criteria of a positive result which they have adopted. The popularity of this antigen is evident from the fact that of the four methods of performing the test recommended in the Interim Report on the Wassermann Test of the Special Committee upon the Standardisation of Pathological Methods of the Medical Research Committee,[5] three employ this antigen and it is stated that (p. 37)—

"Antigen or Extract.—Of the various extracts which have been recommended at one time or another, that prepared from heart and reinforced with cholesterol, as recommended by McIntosh and Fildes, will be found simple to prepare and as satisfactory as any in use at the present moment."

The evidence as to the pre-eminent value of this antigen appears to rest on the extensive tests carried out by Fildes and McIntosh[7] which led them to the following conclusion, which is also quoted in the Interim Report by Harrison:—

"Since no antigen gave a positive reaction in any case in which heart-cholesterin gave a negative, the results have been tabulated as comparisons between heart-cholesterin and the other antigens."

Liver-lecithin plus Cholesterol Antigen.

This, however, ceases to be the case when the liver-lecithin plus cholesterol antigen is used under optimum conditions (see Table). McIntosh and Fildes instituted a comparison between heart-extract, heart-extract plus cholesterol, Wassermann-Meier's fœtal syphilitic liver antigen, and the liver-lecithin plus cholesterol antigen of Browning, Cruickshank, and Mackenzie. It is important to note, however, that as regards the liver-lecithin plus cholesterol antigen, these observers, actuated by theoretical considerations, employed it in a dilution (1 : 20) much exceeding the optimum which was recommended by the original workers (viz., 1 : 8). Hence what McIntosh and Fildes really determined was the unsuitability of this antigen when employed under the conditions which they adopted, and not the inferiority of the method including the use of liver-lecithin plus cholesterol as originally put forward. Walker and Swift,[9] from their results, consider that the antigenic property of cholesterol-heart-extracts is especially evident when testing sera from late (treated) cases of syphilis.

Results of Investigation by Authors.

Recently we have carried out a series of parallel tests, employing liver-lecithin plus cholesterol, according to the usual method (Medical Research Committee's Interim Report on the Wassermann Test, p. 27), and also McIntosh and Fildes's heart-extract plus cholesterol under the precise conditions laid down by these workers as regards dilution and volume of antigen and amount of patient's serum. We have always used varying amounts of complement in both series so as to obtain a quantitative estimate of the complement fixation. The results, while confirming our earlier observation that the liver-lecithin plus cholesterol antigen with *many* positive sera gives a smaller amount of complement fixation than do certain other antigens, e.g., heart-cholesterol, have also shown that *with a proportion of sera which is by no means negligible (nearly 6 per cent.), the liver-lecithin-cholesterol antigen leads to greater complement fixation than does the heart-cholesterol antigen.*† (See Table.)

Table showing Results with the Two Antigens.

Heart-cholesterol.	Liver-lecithin-cholesterol.	Number of sera.	Result.
+	+	125	Agreement in 83 per cent.
−	−	165	
?	?	9	
+	− or ?	15 = 4·2%	Difference of result in 17 per cent.
?	−	1 = 0·28%	
− or ?	+	21 = 5·8%	
−	?	24 = 6·6%	
	Total	360	

We have examined several such sera repeatedly with different specimens of complement and with three different liver products (Thomson, Skinner, and Hamilton's batches iii., vi., and vii.), so that the result may be accepted as of general application. Thus certain sera will be recorded as positive with liver-lecithin plus cholesterol and not with heart-cholesterol, while other sera will be more positive with the latter antigen.

A further point which it is of importance to bear in mind in connexion with further work on antigens, is that not merely may one antigen differ from another as regards optimum concentration, but also that the amount of serum necessary to elicit the maximum complement fixation may vary. Thus, with the heart-cholesterol antigen reduction in the amount of serum, recommended by McIntosh and Fildes, leads to a striking reduction in the amount of complement fixation, whereas a similar reduction does not lead to this effect when liver lecithin-cholesterol is used as antigen.

These results have led us to adopt the following procedure in conducting routine Wassermann tests. For each serum two series of three tubes each are set up: (*a*) containing liver lecithin-cholesterol (1 : 8 turbid emulsion) 0·3 c.cm. plus 0·025 c.cm. patient's heated serum; and (*b*) heart extract plus cholesterol (1 : 30 rapidly mixed emulsion) 0·5 c.cm. plus 0·05 patient's heated serum, along with increasing amounts of complement in each series. Thus the procedure is practically the same as that described by us in the Medical Research Committee's Report except that the heart extract plus cholesterol is substituted for the emulsion of lecithin alone.

We would strongly urge that the uncertainty which at present exists with regard to the significance of the behaviour of certain sera can be best cleared up by a collective investigation concentrated on such cases, and that three classes of material are required: (1) cases of syphilis known to have reacted positively, in which the reaction is becoming extinguished as the result of treatment; (2) untreated cases

† Case 7—see Medical Research Committee's Special Report, Series No. 21—(penile chancre supposedly of 18 days' duration) which reacted positively with liver-lecithin plus cholesterol, but was "practically negative" when tested with heart-cholesterol, illustrates this very well.

of congenital syphilis in which other children of the family or the mother are definitely positive; and (3) cases in which, although there is no clinical suspicion of syphilis, suspicious or positive reactions have been obtained. An extensive selection of negative controls is also highly desirable; these might best be obtained voluntarily from among laboratory workers.

Conclusion.

In the absence of an ideal antigen the present results indicate that a proportion of weak positive reactions will be missed if only a single antigen be employed in performing the Wassermann test. Hence it is advisable always to use *both* antigens. Since all laboratory tests are productive of the most valuable results when the clinician and the laboratory worker collaborate intimately, the desirable procedure would appear to be that, where tests are performed with only one antigen, all sera should be preserved (e.g., by freezing), so that if a positive reaction fails to be obtained in cases which are clinically suspicious, the test may be repeated with the other antigen. Of course, when the reaction is being tested for the control of treatment both antigens should be employed.

THE RELATIVE CONTENT OF

ANTISCORBUTIC PRINCIPLE IN LIMES* AND LEMONS,†

TOGETHER WITH SOME NEW FACTS AND SOME OLD OBSERVATIONS CONCERNING THE VALUE OF "LIME JUICE" IN THE PREVENTION OF SCURVY.

A.—*EXPERIMENTAL INQUIRY*,
BY HARRIETTE CHICK, E. MARGARET HUME, AND RUTH F. SKELTON.

B.—*HISTORICAL INQUIRY*,
BY ALICE HENDERSON SMITH.

(*From the Lister Institute, Director's Department.*)

Introduction.

A BELIEF in the antiscorbutic virtue of the preserved juice of the West Indian lime has long been cherished by the public. Such a faith is, however, not universally shared by those having experience, in recent years, of the value of lime juice for prevention or cure of scurvy. This scepticism is first found in the writings of the Arctic explorers at the end of the nineteenth century (see Jackson and Harley, THE LANCET, April 28th, 1900). It has also been expressed recently by many observers who, confronted with scurvy in one or other of the recent theatres of war, have declared that they found lime juice of no avail as a prophylactic or therapeutic agent. Nevertheless, the literature[1] upon this subject appearing in the eighteenth and early nineteenth century is full of the praises of "lime juice," and there appears to be every reason for believing that the use of so-called lime juice was responsible for the disappearance of scurvy from the British Navy in the first decade of the nineteenth century. The naval records of the period have been carefully searched and the result of the inquiry forms the subject of the second section of this paper. A sufficient explanation of the anomaly will be found to lie in the fact that at this early date the term "lime juice" included the juice of lemons from the Mediterranean, whereas for the last 50 or 60 years it has been applied to the preserved juice of the West Indian lime.

A.—*Experimental Inquiry.*

A study of lime juice has formed an important item in a comprehensive investigation of the antiscorbutic properties of various foodstuffs which has been carried out by a group of workers in this institute during the past two years.[2] This inquiry has confirmed and extended the researches of Holst and his co-workers,[3] published in 1912. Scurvy, in accordance with the view of ancient tradition, has been shown to be a deficiency disease, occasioned by absence in the diet of an unknown accessory food factor, or "vitamine." This factor is present in living vegetable and animal tissues, in largest amount in fresh fruits and green vegetables, to a less extent in root vegetables and tubers. It is present in small amount in fresh meat and milk, and has not been detected in yeast, fats, cereals, pulses. The antiscurvy food factor is sensitive to high temperatures and suffers destruction when the living tissues in connexion with which it is produced are disorganised by drying and other methods of preservation. The expressed juices of fresh vegetables rapidly become impotent in respect of antiscorbutic properties, but Holst and Fröhlich (1912) detected a distinctly greater stability in this respect in the expressed juices of acid fruits.

Experimental.

In studying the distribution of the antiscurvy vitamine among the various foodstuffs the general aim of the experimental work has been to assign to each a definite quantitative value in respect of its antiscorbutic properties. The work has been done mainly with guinea-pigs, though later confirmatory experiments have been made with monkeys.

Young, growing guinea-pigs, 300–350 g. in weight, were selected for the work. If all greenstuff is removed from the diet, and they are nourished on grain (oats and bran) alone, symptoms of scurvy appear after 10–20 days and death takes place in about 30 days. If, in addition, they receive a daily ration (60 c.cm.) of milk, heated at 120° C. for one hour to reduce its original antiscurvy value to a minimum, the general condition of the animal is much improved and growth is maintained for 15–20 days; the onset of scurvy is not, however, materially influenced and death takes place after 30–40 days. (See Chick, Hume, and Skelton, 1918.[4]) The value of fruit juices and their preparations was estimated by adding them in various amounts to this "scurvy diet" of oats, bran, and autoclaved milk, and determining the minimum daily ration required to maintain the animal in health and prevent occurrence of scurvy for a period of 90 days. At the end of this period the animals were killed with chloroform and careful post-mortem examinations were made, followed by histological study of the bony tissues.

There is evidence that the guinea-pig is more susceptible to scurvy than many other mammals, including both monkey and man, and needs a greater proportion of antiscorbutic food in its diet to obtain adequate protection from the disease. But there is every reason to believe that the *relative value* of different foods, as determined experimentally by this means, will remain the same for all, and the results obtained with guinea-pigs have found abundant confirmation in the available historical records of the worth of human diets from the standpoint of antiscurvy value.

Preserved lime juice.—Four samples which had been supplied for official use were placed at our disposal at different times by the authorities. Two were the purified juice of West Indian limes preserved with rum (14 per cent.), one contained no preservative, and the fourth was a sample of Bombay lime juice, preserved with salicylic acid and alcohol. To our great surprise we were unable to detect any significant protection in a daily ration of from 5 to 10 c.cm., which was as large a dose as could be tolerated. It was possible that the age of the samples might be responsible for their inefficiency. The process of "purification" consisted of a lengthy sedimentation and a separation of all pulpy matter expressed from the ripe fruit; this alone involves several months, a fact which, when added to the length of time taken in transport, &c., renders it likely that this lime juice, when consumed, may be many months, even years, old.

Crude lime juice.—Accordingly a series of samples of crude juice were examined; the samples were cloudy and contained a considerable proportion of oily and pulpy matter. They were of various age, but some, at least, were fairly fresh and were examined immediately on their arrival in this country. In two samples only was any antiscorbutic value detected, and in these instances partial protection only was conferred by a daily ration of 5 c.cm.

Fresh lime juice.—In order to eliminate the question of age and to obtain a satisfactory basis for comparison we

* *Citrus medica*, var. *acida*. † *Citrus medica*, var. *limonum*.

investigated the juice of the fresh fruit expressed in the laboratory. This we were enabled to do through the kindness and generosity of Messrs. L. Rose and Co., who supplied us with regular monthly supplies of fresh fruit, specially imported for the purpose. The fresh, ripe fruit‡ was cut in half and the juice pressed out by hand upon an ordinary glass lemon-squeezer, there was little admixture of rind products. It was used as fresh as possible, being kept in a refrigerator. On the arrival of the next consignment of fruit the remainder was rejected and the fresher juice employed; the expressed juice was never more than two months old when administered. Protection from scurvy was obtained with a daily ration of 10 c.cm.; with doses of 5 c.cm. and 2·5 c.cm. a definite degree of protection was manifested, but it was neither constant nor complete. The details of the above results are all summarised in Table I.

TABLE I.—*Antiscorbutic Value of Lime (Citrus Medica, var. Acida) Juice and Lemon (Citrus Medica, var. Limonum) Juice.*

Experiments with guinea-pigs.—Cabbage was removed from the normal diet of oats, bran, and greenstuff and replaced by the fruit juices investigated. A daily ration of 60 c.cm. cow's milk (heated to 120° C. for one hour to destroy anti-scurvy properties) was added to improve the nutritive value of the diet.

‡ These limes were about 4 to 8 weeks in transit owing to war conditions of transport, and it has been suggested to us that this duration of time may have influenced the condition of the fruit unfavourably. We hope in the future to investigate the juice of limes only 2 to 3 weeks old, in order to see if the minimal protective dose for guinea pigs may not be lowered a little with juice obtained from fresher samples of fruit. It is unlikely that any significant alteration in the anti-scorbutic value of the juice will be obtained, as all the fruit employed in the above experiments appeared to be in sound condition. Nevertheless, the point seemed to merit investigation.

Fresh and preserved lemon juice.—Fresh lemon juice was found to be much more potent in respect of antiscorbutic properties. Marked degree of protection was discovered by a daily ration of only 0·5 c.cm., and this was almost complete in some cases with a dose of 1·5 c.cm. With a daily ration of 2·5 c.cm. complete protection from scurvy was attained. The value of fresh lemon juice was therefore estimated at about four times that of fresh lime juice. The lemon juice was roughly of the same age as the lime juice in the above experiment. The lemons were squeezed in the laboratory, the juice was kept in a refrigerator, and its age varied from a few days to two months.

Our experiments with preserved lemon juice are still incomplete, but it appears probable that preservation with sulphite will prove satisfactory in retaining a considerable measure of the original antiscorbutic value. One sample of imported lemon juice from Messina, kindly provided by Messrs. L. Rose and Co., was found to afford distinct protection from scurvy in a daily dose of 5 c.cm. when at least 7 months old.

Experiments with Monkeys.

The question was of sufficient importance to warrant a series of experiments with another experimental animal, and young growing monkeys were selected. After observation for a month or more, to be assured that they were in normal satisfactory health, they were placed upon a generous diet, consisting of various cereal foods with nuts and abundant autoclaved milk, the antiscorbutic element being provided solely by the ration of fresh fruit juice provided. In case of limes the whole fruit was minced in order to include all constituents and the resulting mass squeezed in strong muslin of coarse mesh, yielding a somewhat thick liquid containing pulpy and oily matter. This was done immediately after delivery and at the same time, fresh lemons were procured and their juice expressed. Both supplies were kept in a refrigerator room, until the arrival of the next consignment of limes, when a fresh supply of lemon juice was also prepared. It was thus arranged that the lime and lemon juice used in the experiments (detailed in Table II.) should be comparable as far as possible.

TABLE II.

Experiments with monkeys.—The diet consisted of wheaten biscuit, peanuts, boiled rice, wheat germ, and autoclaved milk (120° C. for one hour) *ad libitum*. The antiscurvy food factor was provided only by the ration of fresh fruit juice.

Results of Experiments in Table II.

Fresh Lime Juice.

1. Good health, until sudden death from acute, undiagnosed illness.
2. Poor health, no symptoms of scurvy, death due to dysentery. P.M. no macroscopic signs of scurvy, histological evidence of slight scurvy.
3. Good health.
4. Acute scurvy, symptoms first noticed 49th day; cured with daily dose of 5 c.cm. lemon juice, beginning 115th day.
5. Scurvy, symptoms first noticed 45th day.
6. Incipient scurvy. Death from dysentery complicated by a worm infection of large intestine. P.M. definite signs of slight scurvy, hæmorrhage in synovial membrane, incipient periosteal hæmorrhage, deformity of rib-junctions.
7. Slow chronic scurvy, complicated with intestinal worm infection.

Fresh Lemon Juice.

8 to 14. Good health.

The fruit juice was, as a rule, acceptable to the monkeys, and the necessary ration, diluted with water and sweetened with sugar, was readily sucked from the nozzle of a syringe. This was not always the case with lime juice, the animals sometimes grew tired of it, and some coaxing was necessary in order to get the ration successfully administered.

The experiments are set forth in Table II., and the results may be summarised as follows: with young, growing monkeys, of 2000–3500 g. weight, daily rations varying from 2·5 c.cm.–10 c.cm. lemon juice never failed to prevent scurvy over periods of time as long as 4 to 7 months. The animals were in excellent health and spirits, and grew in a normal manner.

In case of lime juice the result was otherwise, and the general health of the animals was distinctly inferior. In one case a ration of 10 c.cm. lime juice daily afforded protection from symptoms of scurvy for as long as three months. At the end of this time, however, the animal died of dysentery, and a histological examination of the bony tissues revealed some degree of abnormality. In Experiments 4–7, where the daily ration was 5 c.cm. to 2·5 c.cm., scurvy to a more or less severe degree ensued in every case. Most of these experiments are still in progress.

Experiment 4 is of particular interest. In this case very severe scurvy developed, accompanied by progressive loss in weight. The lower limbs became helpless, wrists and ankles were swollen and tender, the teeth became loose, the gums spongy and hæmorrhagic, and there were distinct follicular hæmorrhages on the face at the base of the whiskers. Finally, blood was passed in the stools and death appeared to be imminent. The lime-juice ration was changed to an equal ration of lemon juice of equal age. In 7–14 days the teeth became firm; gradually all tenderness vanished in the limbs; the animal regained activity and improved in weight. The cure was slow, but the curative dose of lemon juice was small in comparison with the severity of the case.

The relative value of these two fruit juices, deduced from the trials with monkeys, is therefore in accord with that obtained in the experiments with guinea-pigs—i.e., *the value of fresh lemon juice is approximately four times that of fresh lime juice.*

In conclusion, our best thanks are due to Messrs. L. Rose and Co. for generously providing us with a regular supply of fresh lime fruit from Dominica, in spite of the difficulties of transport, &c., occasioned by war-time conditions. We desire also to record our appreciation of their willing coöperation in supplying numerous special samples of crude and preserved juices, and for the accurate and detailed records made on our behalf of the methods used in their preparation. Without this assistance the above research would have been impossible.

B.—*Historical Inquiry*, by ALICE HENDERSON SMITH.

The lime juice now issued to the Navy and Army for their use as a preventive of scurvy is the juice of the sour lime (*Citrus medica*, var. *acida*) grown in the West Indies. To it has long pertained the reputation made in the Navy 125 years ago by the "lime juice" used then. But that "lime juice" was not the juice of the sour lime.

The citrous fruits first used by the Navy came from the Mediterranean, largely from Spain. They did not include the *sour* lime, which is not grown in Europe; they did probably include the *sweet* lime (*Citrus medica*, var. *limetta*), but consisted principally of lemons (*Citrus medica*, var. *limonum*). In 1796 the war cut off Spain as a source of supplies and lemons were brought from Lisbon; the supply was uncertain, insufficient, and very expensive until 1803, when contracts were first made through the naval representative at Malta. Thereafter, for many years, an annual contract secured an ample quantity of the juice of lemons grown in Malta and Sicily. This enabled the Admiralty to employ "lime juice" much more widely than had been done before, and for some years the issue was a general one and not confined, as before, to the sick and to the crews of ships on foreign service. Together with the improvement in victualling and in the general conditions of living on board ships of war this was successful in expelling scurvy from the Navy in the course of a very few years, and by 1810 the records of scurvy cease. From that time the disease has occurred only in isolated and exceptional cases.

Before the middle of the nineteenth century complaints were made about the quality of the lemon juice sent from Malta, but by that time opportunities for the trial of it therapeutically were rare in the ordinary service of the Navy. On the return of Sir James Ross from the Arctic regions in 1849, however, it was shown what disastrous results might follow from a deficiency in the supply. In order that other ships then about to leave England on Arctic service should be assured of a reliable protection from diseases the Medical Director-General caused lemons to be squeezed at Deptford for them, and this provision proved fully adequate. Arrangements were made for the careful supervision thenceforward of all lemon juice bought in Malta.

About 17 years later, when the development of the lime cultivation in the West Indies made available a quantity of lime juice, the Admiralty transferred its contracts, and thereafter issued the juice of limes instead of that of lemons. The essential inferiority of limes to lemons in antiscorbutic power was not suspected, and the new supply was believed to be far better than the old. It was produced by English firms under such conditions as would secure its soundness and purity.

Polar exploration again provided the test of its value; and by comparing the experience of the ships provided with the pure lemon juice in 1850 with that of the first Arctic expedition that took out West Indian lime juice we get a very satisfactory human experiment, demonstrating the relative value of the two fruits. The setting of the comparison is made more precise than is generally to be looked for in historical evidence by the following facts.

The lemon juice for the 1850 expedition was prepared at Deptford, and much attention was paid to the best method of preserving it and for obtaining its maximum value when consumed at sea. The juice was issued to the ships under regulations which insured accuracy and definiteness in the quantity consumed by each member of the crew. The daily ration, 1 oz., was issued to each man individually, and drunk by him in the presence of an officer. In 1875, when Sir George Nares's ships, the *Alert* and the *Discovery*, sailed to discover the North Pole, Sir Alexander Armstrong, who had been medical officer on the *Investigator*, was Medical Director-General of the Navy. So satisfied had he been with the results of lemon juice during the voyage of the *Investigator* that he gave directions that the juice should be issued in precisely the same way on the *Alert* and the *Discovery* as on the previous expedition, that is, in the same quantities, and with the same safeguards against any variation in the consumption of it. But the juice issued to Nares's ships was the "lime juice" from the West Indies.

The two expeditions were so near to one another in time that the general conditions of diet, &c., were very similar; but the later one did enjoy certain improvements of diet suggested by accumulated experience, including double vegetable and fruit rations, additional meat, sugar, &c., and a reduction in the amount of alcohol allowed. In casual supplies of fresh game and herbs there was no outstanding difference. Indeed, every detail of the conditions is very nicely adjusted for the comparison, any difference there was being in favour of the lime juice ships.

And the result was not only clear, but emphatic. Nares's ships, supplied with West Indian lime juice, went out in May, 1875; they had their first case of scurvy in January, 1876. Premonitory scorbutic symptoms showed themselves in a further number of the crews in early spring, but they were not recognised, as scurvy was never thought of as a possible danger. With the starting of the sledge expeditions early in April, 1876, scurvy developed with great severity in the sledge crews and three deaths occurred; concurrently there was a development, only less serious, among the men who remained on the ships. The expedition came home to England in October, 1876.

On the other hand, the *Investigator*, supplied with lemon juice, left England in January, 1850, and got into the ice during the following summer. Throughout the next winter and the spring sledging she had no scurvy. In autumn, 1851, her rations were reduced to two-thirds and her lemon-juice ration was halved, and she still had no scurvy through the following winter and spring. Only in May, 1852, her first case developed, 27 months after leaving home and after seven months of short rations and reduced lemon juice. Other 15 months passed before her crew were rescued, and in that whole period of three and a half years she had three deaths from scurvy, the same number that occurred on Nares's ships within one year.

The conclusion suggested by the history of this long immunity from scurvy during the voyage of the *Investigator* is supported by the history of other ships of her time, while the failure of the lime-juice ration to prevent scurvy on the *Alert* and the *Discovery* is repeated in later cases where it

has been relied on as a protection. In the absence of any other satisfactory explanation of the contrast afforded by the experience of these two expeditions—and the prolonged examinations of the Scurvy Commission of 1877[5] discovered none—*it must be accepted as a very convincing piece of evidence that lemon juice is far more effective than lime juice in the prevention of scurvy. It fully confirms the results of the laboratory experiments which have determined more exactly their relative value for this purpose.*

Summary.

1. The antiscorbutic value of the juice of fresh limes (*Citrus medica*, var. *acida*) has been compared experimentally with that of fresh lemons (*Citrus medica*, var. *limonum*) and has been found to be distinctly inferior. Volume for volume fresh lime juice possesses a potency of about one-fourth that of lemon juice. In one instance severe scurvy developing in a monkey on a diet containing a small daily ration (5 c.cm.) of fresh lime juice was cured by an equal ration of fresh lemon juice.

2. Preserved lime juice was found useless for the prevention of scurvy by the method employed. Experiments with preserved lemon juice are still in progress, but give promise of better results.

3. The experimental results are fully confirmed by a historical study of "lime juice" in connexion with human scurvy. At the period when scurvy was eliminated from the British Navy by its agency the term was used to express the juice of lemons, and it was not until the second half of the nineteenth century that the juice of West Indian limes was adopted in the Navy and Mercantile Marine. The history of two Arctic expeditions, that of the *Investigator*, 1850, and that of the *Alert* and *Discovery*, 1875, has been carefully investigated. The former, supplied with lemon juice, experienced remarkable immunity from scurvy during the first two years of great difficulty and privation; the latter, supplied with lime juice, suffered severely from scurvy at the end of the first winter spent in the Arctic regions.

It should be noted in connexion with these facts that scurvy is a disease with a long period of development. As much as four to eight months upon a defective diet may elapse before definite symptoms of scurvy can be observed.

A CASE OF REPEATED CESSATION OF THE HEART BEAT.

BY E. P. POULTON, M.D. OXON., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, GUY'S HOSPITAL;
AND
H. M. STEWART, M.D. CAMB.

ARREST of the heart for so long as 30 seconds is very uncommon; we have only been able to find an account of one case in which the heart stopped repeatedly.[1] The notes of our case are given below.

The patient, a man, aged 67, was seen by us on March 27th, 1918. He had been healthy all his life; had recently been excited over the war. He had been in the habit of taking plenty of exercise, bicycling up hills, &c. Just before his illness he was carrying some heavy portfolios about the house. No history of specific disease. On March 13th he complained of giddy attacks. His pulse was noticed on one occasion to be 30. He stayed in bed two or three days, but then he got up feeling quite well, but stayed upstairs. During this time he was having two or three short fainting attacks each day. On March 25th, at 2.30 P.M., he began having repeated fainting attacks till 4.30 P.M. The attacks began again at 5.30 and lasted till 7.30. He then got some sleep, but the attacks began again at 10 P.M. and lasted nearly without intermission till his death in the afternoon of March 28th. During the fainting attacks the heart stopped beating.

Clinical features of the attacks.—Between the attacks the patient was sitting up in bed talking perfectly normally. The pulse was bounding; radial artery palpable, but not calcified. On one occasion the pulse-rate was counted at 84 per minute, soon after it had recommenced beating after an attack. It remained at this rate for about 50 or 60 seconds and then it gradually became slower, the rate falling to about 60 or slightly less, the strength being fully maintained. In 86 seconds from the start the pulse suddenly stopped. Immediately the patient grew pale and there was slight cyanosis. The patient went on talking for 2 or 3 seconds, but then fell back on to his right side with a groan. In 5 to 7 seconds consciousness had certainly been lost, but it was impossible to be certain exactly how much earlier this had occurred. Loss of consciousness was followed by contractions of various muscles, and there were involuntary movements of the limbs.

Breathing became gradually deeper and more convulsive, all the accessory muscles of respiration being brought into play. After about 20 seconds the respiration was at the rate of 44 per minute and was extremely deep. This rapid deep breathing was the most noticeable thing about the case at this period. It was more marked than we have either of us ever observed in other pathological conditions. It can only be compared with the convulsive panting which occurs in the severest kind of muscular work. The patient's face was livid and pale. There was no corneal reflex or light reflex.

After 39 seconds, during which no pulse had been felt at all, it suddenly started again, at first rather weakly, but in 5 or 10 seconds it had regained its normal strength, the rate being sometimes over 80 and sometimes between 75 and 80. Within two or three beats the face flushed bright red, and beads of sweat were visible, the conjunctivæ were congested, and there was excess of lacrymal secretion, and very soon afterwards consciousness was completely restored.

The total length of the cycle was on this occasion 125 seconds. On other occasions it was 115 seconds. Roughly it may be said that during every two minutes the pulse completely stopped for 40 seconds. This sequence of events continued with regularity all the time we were examining the case, some 45 minutes.

There was no obvious abnormality about the heart.

The patient was emphysematous and the apex beat barely palpable. There were no murmurs. When the pulse stopped no beat of the heart was audible with the stethoscope; nor was there any sound suggestive of auricular beats. No venous pulsation in the neck was observed. It was unfortunate that no polygraph tracing could be obtained in this case.

Various attempts were made to interrupt the events of the cycle. The patient was told to take some deep forced breaths during the conscious period, but without effect. He then breathed backwards and forwards through a piece of hose pipe, so as to increase the dead space and increase the CO_2 content of the lungs which might stimulate the heart; but again there was no effect. Firm pressure was exerted on the vagi in the neck, smelling salts were applied to the nostrils while the patient was unconscious but without effect. Sal volatile diluted with an equal volume of water was administered by the mouth. Vomiting was produced and the attacks ceased for about 20 minutes, but then they recurred. He died with signs of cardiac failure.

Post-mortem.—Lungs: Congested and œdematous. *Aorta:* Atheroma, particularly in descending thoracic part. *Heart:* Hypertrophy of both left and right ventricles; they contained rather more blood clot than usual. The heart muscle was rather mottled, but did not look very unhealthy; some moderate degree of fibrosis was suspected. The coronary arteries were atheromatous but patent. The aortic and mitral valves were slightly thickened.

Brain.—The vertebral, basilar, internal carotid, and cerebral arteries were all very atheromatous. The brain substance looked healthy.

The abdominal viscera were not examined.

Dr. P. P. Laidlaw very kindly examined some microscopic sections for us.

Sections of the medulla were cut at the middle and upper part of the vagus nucleus. Numerous small hæmorrhages were found throughout the sections, but they were more striking in the immediate neighbourhood of the vagus nucleus. One in particular involved the nucleus itself, but had not destroyed the nerve cells at this point. The vagus nerve cells showed very poor Nissl bodies and the nucleus was occasionally excentric. A few of the cells were vacuolated. The cells form a very great contrast to those of the hypoglossal nucleus alongside. It is doubtful, however, if the appearances indicate a nuclear lesion, since the apparent chromatolysis and the position of the nucleus are both conditions so frequently found in the vagus nucleus that they can be termed normal post-mortem appearances. The vacuolation is, however, abnormal.

Since the hæmorrhages are numerous it is suggested that they are secondary to the repeated asphyxial periods which occurred before death and are not primary. It is impossible to be certain on this point. The arteries at the base of the medulla showed a little atheroma, but this did not appear very advanced, and the smaller vessels appeared normal.

Sections were also taken at regular distances over the lower part of the medulla. No abnormality was seen, and there was no appearance seen similar to those in Neubürger and Edinger's case.

Sections of the vagus nerve trunk did not show any sign of degeneration or any cellular infiltration suggestive of neuritis.

Sections of the heart muscle which were cut failed to show the auriculo-ventricular bundle. It is thus impossible to say whether this was normal or not. The heart muscle showed a little fibrosis at the upper part of the interventricular septum The largest artery in this region showed considerable fibrosis of the muscle and also some intimal overgrowth.

[1] Neubürger and Edinger: Berl. klin. Woch. (1893), xxxv., p. 69, 100.

Discussion.

The case published by Neubürger and Edinger was as follows:—

The patient was a man of 46, who had attacks of unconsciousness which came on after straining at stool. The attacks were of short duration and often repeated. Later on, the free intervals became shorter. The pulse was counted at 12 to 16 for some minutes and it became slower before stopping altogether. On restarting the pulse was more rapid to begin with. The sequence of events was compared with stimulation of the vagus in animals. The post-mortem disclosed congenital absence of the right cerebellar lobe. The myocardium was healthy. The vessels in the neighbourhood of the accessory fibres on one side of the medulla were dilated and varicose. These fibres, according to Heidenhain, probably contain the inhibitory fibres to the heart.

In the present case the fact that no venous pulsation was noticed in the neck, and that there was complete silence on auscultation of the præcordium, suggests that there was complete arrest of the whole heart. The gradual slowing beforehand strongly suggests vagal action. However, this slowing was not so marked as in Neubürger and Edinger's case. A pulse of 30 was noticed some three days before death before the repeated fainting attacks began, and this probably means that there was complete heart-block. This may have been a temporary condition, and may have been followed by attacks of arrest of the whole heart.

Previous descriptions have laid stress on the convulsions that occur after the cessation of the heart beat. So far as we know, no previous description has been given of the enormously increased respiration that we observed. One of us (E. P. P.) has found that the ventilation of the lungs in the severest cases of air-hunger is always less than 20 litres a minute; but in severe muscular work four times this amount has been noted. The respiration observed in this case was quite comparable with the huge ventilation due to muscular work. A similar effect is noticed on ligaturing the carotids in animals. It is presumably due to the stasis of CO_2 in the respiratory centres associated with a lack of oxygen, and since the blood normally arrives at the centre almost fully saturated with oxygen, it would require some seconds after arrest of the heart for the lack of oxygen to be felt. The rapid onset of dyspnœa also suggests a local action on the centres, and it may well be, as Haldane and Douglas have suggested, that the lack of oxygen acts by forming lactic acid locally in the respiratory centre.

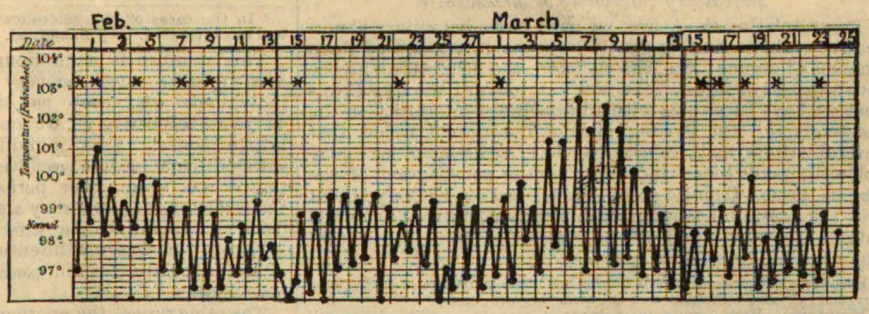
THE SPACING OF INJECTIONS IN THE MAINTENANCE OF A PNEUMOTHORAX.

BY CLAUDE LILLINGSTON, M.B. CANTAB.

IN a retrospect of the development of collapse therapy in pulmonary tuberculosis since it was started in England in 1910 one fact stands out prominently. There has been no great teaching centre or standard work from which the beginner could learn and to which he could subsequently turn for help in difficult cases. The recently published text-book by Dr. Clive Riviere on this subject has therefore met a want. It says much for the intrinsic value of this treatment that it has survived these early vicissitudes. Particularly with regard to the spacing of refills and the total duration of the treatment are the effects of the inadequate teaching of collapse therapy in this country evident. The decision when to discontinue the injections for good requires so much general experience and knowledge of the individual case that it is unsuitable for discussion in a short paper. But the publication of the following case may, perhaps, be useful as a warning against too long intervals between refills.

A man, aged 23, presented on Jan. 14th, 1918, signs of extensive disease of the right lung. The left lung was intermittently crepitant in the second and third intercostal spaces. Sometimes no moist adventitious sounds were audible over this lung. On Jan. 31st the first injection of gas was given, and by the end of February the clinical signs indicated practically complete collapse of the right lung. A few days after the ninth injection, given on March 1st, an acute intercurrent infection sent the temperature vaulting. On this account, and because any extra activity seemed undesirable for the left lung at this critical stage, the next injection was deferred till March 15th, by which date the temperature had become practically normal. After such a comparatively long interval it was anticipated that space for a large quantity of gas would be found. But after only 300 c.cm. had been introduced there was a pressure of +8 cm. of water on expiration. There were no signs of a pleural effusion, but from the root of the lung to its base and round to the axilla and front of the chest respiratory sounds were plainly audible. In the hope that the lower part of the lung had become only loosely adherent to the chest wall, and that the adhesions would give way if a high intrapleural pressure were maintained, injections of gas were frequently repeated, and as high a pressure as + 16 cm. of water was created. With each injection it was, indeed, possible to reduce the air entry on the right side, but not for long. Even the development of a pleural effusion late in April failed to compress the lower half of the right lung, and after May 11th no further injections were given.

This was deplorable, and the only consolation to be extracted from my mistake was the reflection that, owing to the activity of the disease in the left lung, the patient would probably in any case have ultimately fared badly. There are few experiences more disheartening in collapse therapy than to find an otherwise promising case ruined by re-expansion of the lung and its adhesion to the chest wall for lack of timely refills. It is fatally easy to be caught napping when a pleural effusion has developed, particularly when the pneumothorax is incomplete. For as the fluid is reabsorbed the adherent section of the lung appears to act as a base from which adhesions spread to the previously free surface of the lung. But even without a pleural effusion the lung may, as in this case, flap against the chest wall and adhere there, despite every effort to detach it. Looking back on an experience of about ten years and of several hundred injections, I cannot remember a single case under my own care or that of colleagues in which refills were given too frequently. Error to the opposite extreme is, I believe, common, and many a patient's prospects of permanent recovery have been irrevocably impaired. My grateful thanks are due to Dr. Esther Carling for permission to publish this case.



In the chart * indicates injection of gas. In the following table are stated (1) expiratory and inspiratory pressures before injection; (2) after injection; and (3) c.cm. of gas injected.

BLUE SCLEROTICS,

IN CONNEXION WITH OTHER HEREDITARY OR CONGENITAL ABNORMALITIES.

BY DR. N. VOORHOEVE,

LECTURER ON ROENTGENOLOGY AT THE UNIVERSITY OF AMSTERDAM.

EARLY in 1916 I had the opportunity of examining a father (C. W.) and his two daughters, in whom I found the following abnormalities.

Description of Abnormalities.

1. *Brittle bones* (fragilitas ossium).—The individuals were normal and full-grown at birth; they exhibited no abnormalities, and particularly did not suffer from rickets. They enjoyed good health until at two or three years of age the first bone fracture occurred after a very slight trauma. This was soon succeeded by numerous other fractures; the father had 5 and the daughters 13 and 15 respectively. With puberty the frequency diminished and bone fractures only occurred sporadically. Nearly all the fractures healed without leaving any inconvenience; a few healed in a bad position or did not sufficiently consolidate.

With the X rays the entire skeleton exhibited the same abnormalities—viz., a very thin cortex, which stood out sharply from the surrounding tissues; further, it only contained a slight proportion of lime salts and showed a rarefaction of the bone supports and an absence of every rachitical alteration. In certain fractures little or no endosteal, but very strong periosteal, callus had been formed.

We have here characteristic cases of osteopsathyrosis infantilis. As to the cause opinions are still divided.

2. *The blue sclerotics.*—In the two girls the dark grey-blue colour of the sclerotics immediately attracted my attention; in the father they were concealed by pingueculæ. In both the father's eyes was a very marked arcus senilis. Closer examination by Dr. Smit disclosed no further abnormalities in the eyes. It is quite possible that the father, who has an exophthalmia of his left eye, has only his thin sclerotics to thank for it. This exophthalmia showed itself when, about 6 years old, he suffered from "glands in the eye." He now has besides maculæ corneæ with consequent irregular astigmatism, a myopia of 10 D., and a small sickle in the fundus.

3. The father suffers from hæmophilia. The two girls do not.

Hereditary Inferiority of Mesenchyme.

Recapitulating the above, we have three hereditary abnormalities which find expression in the inferiority of three systems of organs—viz., the skeleton, the sclerotics, and the blood-vessels or blood. We now put forward the hypothesis that we have here to do with an hereditary inferiority of the mesenchyme. On looking up the literature I found that several writers had conjectured that fragile bones and blue sclerotics point to an inferiority in the constitution of the fibrous tissue. Definite proofs were, however, entirely absent and the question has never been clearly postulated or looked into. The organs and tissues descended from the mesenchyme are shown below.

Ectoderm.—Epidermis with its derivatives; central and peripheral nervous system; epithelium of the sense organs; lens.
Mesoderm.—Back segments (voluntary muscles); side plates (all epithelium of urogenitary system, epithelium of pleuro-peritoneal cavity).
Entoderm.—Epithelium of entire intestinal canal with appendages (liver, pancreas, lungs, &c.); epithelium of bladder; gustatory papillæ.
Mesenchyme.—Skeleton; sclerotics; heart, blood-vessels and blood, ? spleen, ? lymph glands and vessels; fibrous tissue, ligaments, involuntary muscles.

The question arises whether the patients exhibit other phenomena which would point to abnormalities in, or to inferiority of, the mesenchyme organs. In the father we find a premature degeneration of the corneæ (arcus senilis) and of the blood-vessels (severe arterio-sclerosis at 54 years of age), besides which the ears stand right out from the head. In the elder daughter the jaws are too small and the lateral incisors are planted inwards. Both little fingers are in radial adduction to the metacarpo-phalangeal joint. All three patients are of slender build and small size and the palate is very high. No further abnormalities were found in the patients, who are very intelligent. The father has scars of tuberculous fistulas in the neck and shows retraction of the top of the left lung.

Inquiry into the Members of the Family.

The patient could furnish information concerning no fewer than 244* members of his family, extending over five generations. Consanguinity did not occur nor any trace of lues.

Of the 244 members of the family 59 are here represented in a genealogical tree. I was enabled personally to interrogate or examine 40 of them. In order not to impede the general view the Groups (*a*), (*b*), and (*c*) have not been included in the diagram.

Group (*a*): Containing father and mother of (*a*), his brothers and sisters and their descendants. Information could be got about 83 individuals of this group. Among them I mention: 1† *hæmophilia* (son of daughter of ancestors); 1† epilepsy; 7 cases of tuberculosis.
Group (*b*): Containing father and mother of (*b*), her brothers and sisters, and their descendants. Information could be got about 69 individuals of this group. Among them I mention: 1† congenital deformity of heart (grandchild of ancestors); 1† born lame, 1† dwarf (great-grandchildren of ancestors); 1 hunchback; 6† tuberculosis.
Group (*c*): Containing father and mother of (*c*), her brothers and sisters, and their descendants. Information could be got about 33 individuals. Among them I mention: 2 hunchback (children of ancestors); 3† lymph gland tuberculosis (2 children and 1 great-grandchild of ancestors); 1 severe rachitis (grandchild of ancestors).

Observations with regard to Groups (*b*) and (*c*) I shall omit. In Group (*a*)—that is, the grandfather of my patient and his descendants, excluding the branch of my patient's father—there is an individual, the son of a daughter of the sire of the family, who died from hæmophilia at the age of 8. We may assume that Group (*a*) conceals even more individuals suffering from hæmophilia, but in any case the hæmophilia, which recurs in later generations, is due to the ancestral pair which head this group.

A list is given of the various congenital and hereditary abnormalities exhibited by the individuals in this genealogical tree.

(1) C.W. + brothers and sisters. (2) C.W. + 3 children. (3) 59 members of the family (including C.W. and children). (4) 33 members of the family (excepting C.W. and children).

—	(1)	(2)	(3)	(4)
Number of individuals	6‡	4‡	59	33
Blue sclerotics	1	3	4	1
(Blue sclerotics*)	(3)	—	(7)	(7)
Brittle bones	1	3	3	—
Hæmophilia	2	1	4	3
Cong. vit. cord.	—	—	1	1
Cleft palate	1	—	1	1
Rachischisis	—	—	1	1
Total abnormalities	5 (8)	7	14 (21)	7 (14)
Individuals affected	5	3	9 (16)	6 (13)
Abnormalities per individual	0·84 (1·33)	1·75	0·24 (0·36)	0·13 (0·26)

* In the cases of blue sclerotics given in brackets the discolouration was less intensive. ‡ Examined.

This number is a minimum and would probably prove even greater after a very careful examination. Two individuals who each had a bone fracture (at 12 and 44 years respectively) are not indicated as suffering from brittle bones. Two individuals are marked as having suffered from severe rachitis; it is not at all impossible that it was some other, perhaps hereditary, abnormality of the skeleton, and we may also ask whether severe rachitis does not point to an inferiority in constitution of the skeleton. It was my intention only to employ the fixed minimum of the certain cases of inferiority as the basis for my remarks.

The table proves the enormous number of congenital abnormalities of the mesenchyme organs in this family. We have before us a family in which hæmophilia occurs hereditarily. But the inferiority of blood and blood-vessels is not seen exclusively in the presence of hæmophilia; a congenital defect of the heart shows in what a labile equilibrium the constitution of this organic system is found. Brittle bones do not yet occur, but the constitution of the skeleton already shows signs here and there of labile equilibrium; the cleft palate and rachischisis are there to prove it. Blue sclerotics, although less intensive than in my patients, are already found in several individuals, and one of them has, besides, an embryotoxon.

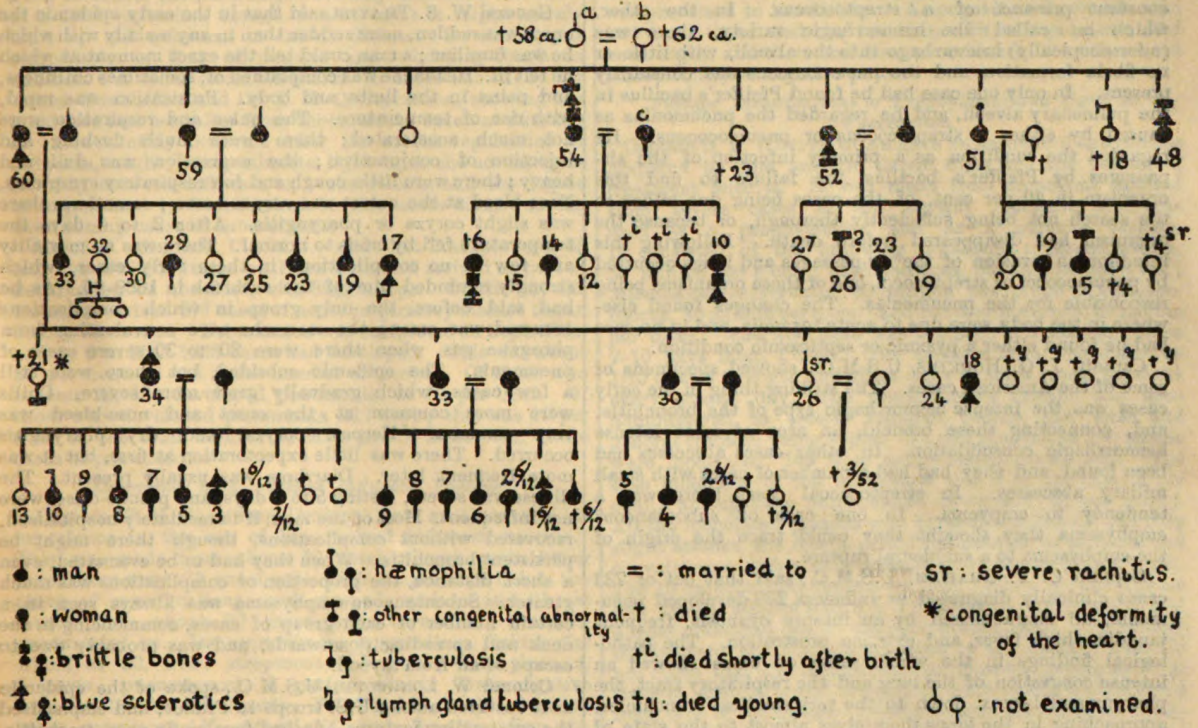
All the abnormalities above described relate to the mesenchyme organs, but of certain mesenchyme organs no abnormalities are here mentioned. These are the spleen, the lymph glands and vessels, the fibrous tissue, the ligaments, and the involuntary muscles. The descent of the

* Infants that died before attaining the age of 2 years are not taken into consideration.

spleen from the mesenchyme is very doubtful, and we know so little about its physiology that it would not be surprising if an inferiority of this organ had not been found clinically. As to the lymph glands and vessels, the number of cases of lymph-gland tuberculosis in this family is striking, whereas the relation of frequency between tuberculosis of the lymph glands and that of other organs is very large. Possibly the diminished resistance of these organs against infection with the bacilli of tuberculosis must be considered as a sign of inferiority. Finally, it is not remarkable if inferior tissues concealed in the body, when their functions are not of great importance, do not show any appreciable abnormality. Further, I need only mention that many women, and also some of the men, belong to the type of the so-called habitus atonicus, without deciding whether this should be considered as a proof of congenital inferiority of the ligaments.

On summing up the above, I am of opinion that the grounds here developed form a strong support for the hypothesis of an hereditary inferiority of the mesenchyme.

Genealogical Chart Illustrating the Inheritance of Blue Sclerotics, &c., through Four Generations.



A possible objection is that the inferiority of these systems of organs was due to some deficient organ or other. The thought of an organ with an internal secretion naturally suggests itself. Such an organ is, however, not only unknown, but its existence is improbable. Moreover, even after a very careful examination of these patients no single abnormality of any of the blood-glands was discovered.

Significance of the Hypothesis.

The presence of an hereditary inferiority in one of the four groups in which the embryonal cells are differentiated in the very earliest stage of development is of far greater general significance than to give an explanation of the origin of the abnormalities found in this family. It is a working hypothesis. It seems to be very important to follow up the combinations of hereditary abnormalities with other symptoms of degeneration in one and the same family. Have such hereditary inferiorities of the whole or of the greatest portion of the mesenchyme been known to occur? Can they likewise be restricted to one germinal layer to the exclusion of the mesenchyme and of the two other germinal layers? Numerous examples appear to point that way.

Among many questions I shall only mention one more: How far can the degeneration of a germinal layer or of the mesenchyme proceed in a family before the other germinal layers also begin to degenerate? In January, 1916, Professor van der Hoeve stated at the Medical Society at Groningen that, together with de Kleyn, he had discovered deafness as an accompanying symptom of brittle bones and blue sclerotics. Professor Burger examined the ears of two of my patients and of two members of their family. All four suffer from typical *labyrinthine deafness*, an hereditary ailment *par excellence*, but an affection of an ectoderm organ. On the other hand, van der Hoeve and de Kleyn and also Bronson found in their patients otosclerosis (mesenchyme), although both the two former and the latter observed in one patient a combination of otosclerosis and labyrinthine deafness. According to the investigations of Kishi, Quix, and van Lennep the atrophy of the Cortian organ in certain labyrinthine abnormalities (in the dancing mouse, for instance) is most probably caused by a primary affection of the stria vascularis, a product of the mesenchyme. The possibility is, at any rate, presented that the affection of the labyrinth in my patients is a further proof of an inferior mesenchyme.

This example shows that an examination based on this working hypothesis may present difficulties, and there is no doubt that their number will not be small. I need only mention the critical classification of congenital and hereditary abnormalities, of symptoms of inferiority in constitution and pathological abnormalities *sensu strictiori*, especially when these occur in the individual in the embryonal stage. Further, a high degree of discernment will be required to distinguish between an abnormality and its inevitable result on the one hand and two consequences of one and the same cause on the other. Moreover, descriptive embryology has yet many secrets to reveal and the experimental branch of this science is still in its infancy, whereas anatomy, physiology, and pathology will but too frequently be unable to furnish the so ardently desired information. But this is no reason why one should allow the explanation of the spontaneous experiments exhibited in nature to pass by with a *non possumus*. If the inductive method does not lead us to the goal, we may at least expect that the deductive method will create numerous questions and points of view the answer to which will add an inducement to prosecute the search. If this hypothesis, even if it should prove to be incorrect, can in any way further this end it will not have been fruitless.

ROYAL SOCIETY OF MEDICINE.

Resumed Discussion on Influenza: Morbid Anatomy.

IN continuing the discussion on influenza which was reported in THE LANCET of Nov. 23rd (p. 704), Dr. B. H. SPILSBURY, discussing the morbid anatomy of the condition, gave an account of the post-mortem findings of 20 fatal cases, 15 occurring in persons between 10 and 37 years of age, the remainder being infants. The most constant condition found was acute inflammation of the air-passages of the vivid "flaming" variety, with abundant purulent exudate in the upper air-passages. He had found an organism having the morphological characters of Pfeiffer's bacillus in the air-passages in 12 out of the 20 cases. In 16 cases there was acute broncho-pneumonia of two types. The first variety was a typical acute suppurative bronchopneumonia, with a tendency to abscess formation and the constant presence of a streptococcus. In the other, which he called the hæmorrhagic variety, there was (microscopically) hæmorrhage into the alveoli, with little or no fibrin formation, and the pneumococcus was constantly present. In only one case had he found Pfeiffer's bacillus in the pulmonary alveoli, and he regarded the pneumonias as caused by either a streptococcus or pneumococcus. He regarded the condition as a primary infection of the air-passages by Pfeiffer's bacillus, the failure to find this organism in 40 per cent. of the cases being due either to the search not being sufficiently thorough, or because the organism had disappeared before death. Following this infection an invasion of the air-passages and lungs occurred by pneumococci or streptococci, one of these organisms being responsible for the pneumonias. The changes found elsewhere in the body were due to acute toxæmia, and in no case had he found either a pyæmic or septicæmic condition.

Captain J. G. HOPKINS, U.S.M.C., showed specimens of some of the American cases. The striking thing in the early cases was the intense hæmorrhagic type of the bronchitis, and, connecting these bronchi, an area of most intense hæmorrhagic consolidation. In other cases abscesses had been found, and they had had a number of cases with small miliary abscesses. In streptococcal cases there was a tendency to empyema. In one case of subcutaneous emphysema they thought they could trace the origin of the emphysema to a subpleural rupture.

Captain C. F. GRAHAM, U.S.M.C., said that out of 723 cases clinically diagnosed as influenza 239 developed pneumonia, all characterised by an intense cyanosis, frequent jaundice, high fever, and extreme prostration. The pathological findings in the whole series of cases showed an intense congestion of the lung and the respiratory tract, the pharynx and larynx, down to the very smallest bronchioles, approaching in the lungs themselves almost to the state of hæmorrhage. The very frequent presence of the hæmolytic streptococcus gave rise to their conception of the situation—that the streptococcus was the organism most commonly concerned.

Clinical Picture: Bacteriology.

Surgeon-General Sir BERTRAND DAWSON, speaking from the clinical side, said that although the onset was generally acute it might be subacute or insidious, and the disease might start in the throat and not in the nose. The graver form might come on immediately or as late as the sixth day. The seriousness of the cases depended for their characteristics upon the relative prominence of (1) the septicæmia, and In that of the septicæmic cases the patient is in the lying (2) the amount of involvement of the respiratory tract and its nature. In each type the clinical picture is distinctive. posture, breathing quickly, and of a blue colour approaching heliotrope, but there is no true dyspnœa; the patient is fully aware of his surroundings; the heart is rapid and the blood pressure low; there are no physical signs in the lungs except perhaps a few scattered rhonchi, and there is no sputum. There may be purpuric patches and perhaps subcutaneous emphysema. The pulmonary varieties include the broncho-pneumonic cases, hæmorrhagic or suppurative, with dullness, tubular breathing, and increased vocal resonance. Where bronchitis dominates the patient looks obviously ill and suffers from respiratory distress; in the lungs there are scattered rhonchi and large areas of silence; the percussion note is high-pitched and resonant, and the patient is sucking in the lower intercostal spaces; the bronchi are filled with purulent glutinous exudate. In the pulmonary type the findings are the same as in lobar pneumonia. He thought that the difference in the result of bacteriological investigation was due in part to the different methods employed, the difficulty in finding Pfeiffer's bacillus, and the date of the disease on which the examination was made. Evidence tended to show that Pfeiffer's bacillus did play a dominant part; its rôle was a pioneer one in that it prepared the way for other organisms. Its habitat was limited, but it might penetrate deeply, though not to any great extent. With regard to the other organisms, their morphology mattered less than their virulence. In the virulent cases the streptococcus was more often found than the pneumococcus. Diplococci were also found in some cases, and sometimes, on frequent subculture, returned gradually to the pneumococcal form.

Colonel H. FRENCH'S pictures, which were taken at Aldershot, were then exhibited, showing the flushing and cyanosis.

Experience of U.S. Medical Officers.

General W. S. THAYER said that in the early epidemic the onset was sudden, more sudden than in any malady with which he was familiar; a man could tell the exact moment at which he felt ill. Headache was complained of, sometimes chilliness, and pains in the limbs and body. Prostration was rapid, with rise of temperature. The pulse and respiration were not much accelerated; there were much flushing and injection of conjunctivæ; the expression was dull and heavy; there were little cough and few respiratory symptoms. Nose-bleed at the outset was very common; sometimes there was slight coryza or pharyngitis. After 2 to 4 days the temperature fell by crisis to normal. There was no mortality and few or no complications in these early cases, which strongly reminded him of the outbreak in 1889–90. As he had said before, the only group in which complications occurred was among the men who were convalescing from phosgene gas, when there were 20 to 30 severe cases of pneumonia. The epidemic subsided, but there were still a few cases, which gradually grew more severe. Chills were more common at the onset and nose-bleed was very common. Herpes, coryza, and dry pharyngitis occurred. There was little expectoration at first, but it was more frequent later. Diarrhœa was usually present. The illness was severe, lasting 5 to 6 days, and pseudo-crises were not infrequent. Most of the men, if immediately hospitalised, recovered without complications, though there might be persistent bronchitis. When they had to be evacuated, even a short distance, the proportion of complications was much greater. Subcutaneous emphysema was always seen in a certain number of each group of cases, commencing in the neck and spreading downwards, and was probably due to escape of air from alveoli.

Colonel W. LONGCOPE, U.S.M.C., spoke of the epidemic as it occurred among U.S. troops in France, and emphasised the outstanding features—flushed face, puffy eyes, tracheitis, pains in back and in joints and bones and occasionally in muscle, the tenderness of the leg muscles being extremely noticeable. He had the impression that there were two infections—a primary infection and an infection of the respiratory tract, usually pneumonia. He drew attention to two other features. The patients at Brest, who had just landed from the boats, were emaciated, cyanosed, delirious or in coma, and always died. This was probably due to the difficulty in treating on board. In the subacute cases râles and expectoration (purulent) persisted, though the patients were much better. X rays showed scattered shadows throughout the lung. These patients might possibly recover, though some bronchiectasis would remain. Immediate hospitalisation was necessary. Segregation and isolation were equally important, by means of which hospitals had been able to prevent the spread of the disease. In one hospital the patients were segregated according to the germ found. They were at first isolated, and those in whom streptococci or pneumococci were found were placed in another room, as a result of which very little pneumonia developed.

Etiology.—Pulmonary Tuberculosis as a Late Complication.

Mr. HERBERT TILLEY said that in other epidemics pneumonia was regarded as a secondary infection, spreading from the upper air-tracts, whereas in this epidemic he had seen very few cases of complications in the upper respiratory tract, although pus had been very frequently found post

mortem in the sphenoidal sinus. He thought that Pfeiffer's bacillus opened the way in the upper air-passages, and then the pneumococcus, which was always present in the healthy nose, spread to the lungs.

Dr. R. MURRAY LESLIE said that practically no reference had been made to a very formidable late complication—pulmonary tuberculosis. A large number of cases occurred exhibiting symptoms and signs of tuberculosis, including positive bacillary sputum, some months after an attack of influenza. He had had under his care at a metropolitan military hospital during the past few months young soldiers who showed symptoms and signs of tuberculous disease within periods varying from a fortnight to four or five months after an attack of influenza, some of the influenzal histories coinciding with the April and June epidemics at the front. He thought that true influenza often acted as the spark which lights up the conflagration, and that it was a wise precaution to be doubly careful in the convalescent stage of influenza in the case of patients with a constitutional or family predisposition to tuberculosis. In a few instances influenza might actually determine the onset of a fresh infection, though in most cases it might merely light up old quiescent or latent disease. Its action was comparable to that of measles and whooping-cough in children. A series of curves similar to those shown by Sir Arthur Newsholme and Dr. T. H. C. Stevenson, showing the incidence and mortality from tuberculosis, taken at monthly or three-monthly intervals after the recent epidemics of influenza, might throw valuable light upon the actual relationship between influenza and tuberculosis, and the degree of importance to be attached to this acute disease as the determining cause of tuberculosis.

Major F. MEADER, U.S.M.C., said that Transport No. 56 left the United States on Sept. 14th and arrived at port of debarkation on the 21st, with 5951 troops. On the day the transport arrived 574 cases of acute respiratory disease began among the troops. Debarkation was completed on Sept. 25th, and by Oct. 25th 1688 cases had developed. This was about 28 per cent. of the total number of troops. Of those who became ill, 534 developed pneumonia, or 32 per cent. Of those who developed pneumonia 317 died; this was 19 per cent. of the total number of cases and 59·3 per cent. of the cases of pneumonia.

Experience with "Mixed Influenza Vaccine."

Captain W. E. CARNEGIE DICKSON gave an account of his experience in the use of his "mixed influenza vaccine." This was made from about 50 cases, throat swabs being taken from some 20 cases with high temperature before the onset of complications, and washed sputum and throat mucus from about 30 cases with bronchitis, broncho-pneumonia, &c. Its approximate composition, taking the whole at 20, was: streptococci, 5 parts; staphylococci, 5 parts; pneumococci, 3 parts; minute Gram-negative influenza-like bacilli, 3 parts; Friedländer's bacilli, 2 parts; other organisms (*M. catarrhalis*, &c.), 2 parts. For prophylactic use 60, 100, and 150 millions were given to adult males at weekly intervals, 40, 60, and 100 millions to adult females, and the amount of reaction produced by these doses appeared suitable in the majority of cases. After testing the dose on healthy persons it was tried on influenzal cases with temperature but no pulmonary complications. The results were considered beneficial, in most cases apparently the disease was shortened and the occurrence of complications was prevented. The vaccine was then tried on cases of purulent bronchitis, broncho-pneumonia, &c., beginning with doses of 20, 40, 60, 80 millions, at intervals of 3 to 4 days according to the severity of the case, with some success when the patients were not actually moribund, though there were not yet a sufficient number of cases upon which to base a scientific opinion. He had given the vaccine prophylactically to about 150 persons, and, so far as he could ascertain, only two had developed anything resembling influenza, and these were doing well. Captain Dickson also referred to the question of the influenza carrier. In his hospital practice one of the most noticeable features was the frequent occurrence of small Gram-negative influenza-like bacilli in many of the cases of chronic bronchitis in which, clinically, the suspicion of the presence of influenza had not arisen. They conformed culturally and morphologically with Pfeiffer's bacillus, and these patients constituted, he was convinced, the reservoir of influenzal infection in this country.

Prophylactic Vaccination.

Surgeon-Captain P. W. BASSETT SMITH, R.N., gave an account of the prophylactic vaccine which had been prepared in quantity at the Royal Naval College, Greenwich, and distributed to the depôts and to ships of the Grand Fleet to be given to all on a voluntary basis. Its composition was as follows:—

B. influenzæ (3–5 strains)	60 million per c.cm.
Streptococci (,,)	40 ,, ,,
Pneumococci (,,)	200 ,, ,,

Dose: 1st inoculation, 0·5 c.cm.; 2nd inoculation, 1 c.cm.

In sending out the vaccine directions were given that it was not to be used if acute catarrhal symptoms or fever were present. One medical officer reported that in the course of the inoculations 10 cases occurred. Four of these had received one dose on the day of onset only. All ran a very mild course. Of the 6 not inoculated 2 were mild and 4 severe, with one death. This pointed to the value of the vaccine even in the early stage. At Greenwich 1000 boys at the Royal Hospital School had received both inoculations and no case had occurred among them, though the disease was prevalent in the district. Amongst the thousands who had been inoculated the reaction, with one exception, had been slight, and there had been no evidence of an increased susceptibility or negative phase.

Further Investigations of Prophylactic and Curative Vaccination.

Captain H. E. WHITTINGHAM gave an account of the vaccine prepared by him and Dr. Carrie Sims and the results of treatment with it. It was made from organisms isolated from severe cases in the present epidemic and was used as a prophylactive and as a curative vaccine. It consisted of the following organisms: Streptococcus, 50 million per c.cm.; pneumococcus, 50 million per c.cm.; *Micrococcus catarrhalis*, 50 million per c.cm.; meningococcus, 20 million per c.cm.; and *Bacillus influenzæ*, 20 million per c.cm. The first dose was ½ c.cm., the second, given 7–10 days later, 1 c.cm. The curative dose was made up 1/10 of this strength and given daily in some cases, in others every second day. The prophylactive vaccine had been administered to several hundred people, the local and general reaction being slight. In one institution 156 people were inoculated, 149 were uninoculated—total 305. The case incidence of the inoculated was 8 in 156 (i.e., 5 per cent.), amongst the uninoculated 18 in 149 (12 per cent.). All the inoculated persons who developed influenza had only slight attacks, the febrile period terminating in 48 hours and convalescence being well established by the end of a week. The 18 uninoculated persons who fell victims to the disease had typical attacks with a 5–7 day course in the milder and a more prolonged one in the complicated cases. Pulmonary involvement was distinct in seven of the cases. They did not claim that the vaccine was an absolute preventive, but thought that it would abolish or modify considerably the toxic type of the disease. The dose used as a curative vaccine was in all cases 1 c.cm., containing 5 million each of streptococcus, pneumococcus, and *M. catarrhalis*, and 2 million each of meningococcus and *B. influenzæ*. The first injection was given as soon after admission as possible and repeated daily until the temperature fell to normal. The results showed that cases which were seen early might have their course cut short by a large dose of the vaccine before toxæmia had time to set in. In toxic cases, or those with high pyrexia, antistreptococcal serum 20 c.cm. was given, and 10 c.cm. thereafter daily for 3 to 4 days; vaccine might be given also. As regards serum treatment, cases treated early in the disease had a far greater chance of recovery than those treated late. All cases were severe. Of those injected with serum before the sixth day all recovered—i.e., 6 out of 6, whilst those injected after that day—6 all told—died.

Serum Treatment.—Salicin.

Major G. NEWTON PITT, R.A.M.C., said that hæmorrhagic sputum occurred with streptococcal infection, rusty sputum with pneumococcal, and purulent sputum was invariable with streptococcal infection combined with that of *B. influenzæ*. He regarded the toxic and lethargic cases as almost hopeless from the first. He had seen some benefit occasionally in the lethargic and toxic cases from antistreptococcal serum, 20–40 c.cm.

Lieutenant-Colonel C. E. COOPER COLE, C.A.M.C., spoke of 125 cases treated by polyvalent antistreptococcal serum as supplied by Burroughs and Wellcome or Parke, Davis & Co.

The best time for administration was the earliest possible after onset. Early mild cases cleared forthwith. In extremely toxic cases there appeared to follow a reduction in the toxæmia; many patients who appeared about to die in two or three days held on for about ten days.

Mr. E. B. TURNER gave his experiences of treatment by salicin, which seemed to have a remarkable effect in cutting short the disease, preventing complications, and destroying the infectivity of the patient. The longer the treatment was delayed the longer the disease lasted. Very large doses were necessary (ordinary doses being quite useless), so that from the beginning the patient was drenched with salicin. He began by giving 20 gr. hourly for 12 hours. Less than this was of no value. It was best given in a cachet. He had tried salicylate of soda, but the effect was not so good. There was buzzing of the head and sometimes delirium. He had used these large doses of salicin in patients with heart disease with no ill-effects whatever.

MEDICAL SOCIETY OF LONDON.

Inheritance and Acquirement of Disease: A Study of the Rejected.

A MEETING of this society was held on Nov. 25th, Dr. A. F. VOELCKER, the President, in the chair, when Colonel J. G. ADAMI, C.A.M.C., gave an address on the Physical Census.

With the onset of the war, Professor ADAMI said, we were fully prepared for the preliminary physical examination of the would-be soldier, and when from voluntary we passed to what may be termed, if not "impressed," certainly "impressive" service, and from this to conscription of all men of serviceable age, it was scarcely noticed that at a bound we had established, under the Ministry of National Service, a physical census of the active manhood of the British Isles, and in November, 1917, for the first time, had placed ourselves in a position to gain a comprehensive grasp of the quality of that manhood, of its efficiency and its deficiencies. No civilised country has so dense a population, and none so large a section of population which for an equal number of generations has led a factory existence with all its known attendant effects upon the physical well-being of the individual and his offspring. The figures collected have not yet been fully analysed, but certain National Service Commissioners have already made the necessary analyses for their districts, showing results gravely below the average. Thus for a small West Midland group of those of 18 years one Commissioner finds 660 per mille in Grade I. From a Northern city another obtained 531; in a busy manufacturing town of the Midlands the number was 573; whereas in certain Midland country districts it rose to 805 and 819 per 1000. With such figures as these last it cannot be said that Dr. Keith has placed too high his "Bogey," based on an analysis of the measurements of 1000 Cambridge students.[1]

Statistics of a Representative Section of England.

I am indebted to Sir James Galloway for the monthly statistics for the first half of this year of all the districts in a representative section of England—representative in that it embraces areas which are some of them predominatingly agricultural, others mining, others industrial, among the latter one of the greatest textile centres, and one of our most noted centres for munition factories and workers in metal; along with these there is an important seaport. Taking the Grade I. men alone for April, we have the following figures:—

—	No. examined.	No. Grade I. per mille.
A mining area	7030	703
A munition (metal work) area	8919	660
An industrial area (cotton, jute, &c.)	5295	623
An agricultural area	2871	613
A seaport and shipping area	1238	491
A textile area (woollens)	5001	405
A textile area („)	2933	384

Here, granting that we deal with men of the same age-period, we have indications to an even greater extent of the loss of effective man-power in certain classes of the community, and these indications are supported by the fact that it is not in one month's returns only, but month after month the proportion of Grade I. men are materially lower in certain districts than they are in others. The indications are those of a condition so serious that for this reason alone it is essential that the Ministry of National Service continue its work after the war, if only to probe thoroughly into this matter of the relative health and efficiency of our manhood in different districts engaged in different occupations. As a basal investigation it is evident that what is now needed is an analysis of the medical history sheets for 1918, if not of the whole country, at least of areas devoted to special pursuits, or, better still, of those engaged in special occupations, in order to observe the primary condition of those engaged and the progressive effect of those occupations upon the physical state of the workers. We need an analysis of the physical state of, say, 1000 workers in each important occupation belonging to the quinquennia 18–23, 23–28, 28–33, and so on. With this we will possess a sound foundation, and provided with this we will for the first time be able to make positive statements regarding the state of our adult population.

Causes of Rejection in an Industrial Area.

Between Jan. 1st and June 30th, 1918, 24,281 men between the ages of 18 and 51 were examined in a large Yorkshire town. Of these, 1770 (or 72·8 per mille) were placed in Grade IV. There were in addition 74 class M. men so "obviously unfit" that medical examination was dispensed with. It is to be noted that in this area several thousands of miners were called up for examination up to the age of 35 years, and the Deputy Commissioner calls attention to the fact that the majority of the rejections occurred between the ages of 20 and 30. I have arranged his data, not as he did according to relative frequency, but in classes according to the cause of rejection.

Analysis of Main Headings of Causes of Rejection in 1844 Cases in an Industrial (Mining) Centre.

I.—*Infections and their Results.*

—	No. of cases.	Percentage of rejections.	Percentage of total examined.
Tuberculosis (Pulmonary tuberculosis, 468 cases or 25·3 per cent.)	584	31·6	2·3
Valvular disease of heart	188	9·0	0·7
Infantile paralysis	69	3·7	0·29
Otorrhœa	41	2·2	0·17
Chronic bronchitis	39	2·1	0·15
Rheumatoid arthritis	26	1·4	0·1
Disordered action of heart	10	0·5	—
Totals	957	50·5	—

II.—*Injuries and Occupational Conditions.*

Amputations	104	5·6	0·42
Varicose veins	98	5·3	0·4
Injuries (head, back, and extremities)	81	4·9	0·33
Opacity of cornea	12	0·6	0·04
Miner's nystagmus	11	—	—
Flat foot	11	0·6	0·04
Hallux valgus	11	0·6	0·04
Ventral hernia (post-operative)	7	0·4	0·02
Totals	335	18·0	—

III.—*Nutritional and Chronic Disorders and Intoxications.*

Chronic nephritis	48	2·6	0·19
Knock-knee	11	0·6	0·04
Cataract (excl. congenital)	10	0·5	0·03
Amblyopia and amaurosis	6	0·3	0·02
Exophthalmic goitre	1	—	—
Totals	76	4·0	—

IV.—*Conditions in the Main of Antenatal and Natal Origin.*

Epilepsy, major and minor	70	3·7	0·29
Idiocy and arrested mentality	53	2·8	0·2
Talipes	18	0·9	0·07
Myopia	18	0·9	0·07
Dumbness	10	0·5	0·03
Diabetes	6	0·3	0·02
Neurasthenia	5	0·2	—
Other inherited and congenital conditions	11	0·6	—
Totals	191	10·0	—

V.—*Conditions in Part of Antenatal Origin, in Part Nutritional, Occupational, or Infective.*

Curvature and deformity of spine	34	1·9	0·14
Poor physique	30	1·5	0·13
Inguinal hernia	11	0·6	—
Totals	75	4·0	—

[1] THE LANCET, Oct. 19th, p. 542.

The outstanding feature in this analysis is that eminently preventable causes constitute much the greater portion of the headings. Infectious disorders and their results constitute more than half, tuberculosis of all orders roughly one-third, pulmonary tuberculosis just over one quarter. Here in an industrial centre injuries and amputations constitute one-tenth of the causes. What I would urge as the programme for the new future is: Continue the physical examination of young manhood; from its results determine where we are at fault, ruthlessly wage war against those conditions which lower the vitality of our people, and thereby raise the general level of health and strength of our people. And with this, by the establishment of adequate grading, recognise and encourage the best and strongest among our people to the end that, mating worthily, they may propagate a sound, strong stock, and lead in the improvement of the race.

Discussion.

Sir JAMES GALLOWAY referred to the need for secrecy during the war concerning the strength of the drafts for the front which the country was able to send, for no civil department's information would have been of more value to the enemy. The facts supplied to the Premier, on which he based his remarks on the nation's physique, may have been given with the same predominant idea, though Mr. Lloyd George's instinct enabled him to approach surprisingly near to the truth. At that time, however, our enemies were too much concerned with the immediate prospect to pay much attention to that declaration. Now that hostilities were at an end the information which had been collated during recruitment, and which was now being collected and analysed by the Scientific Committee of the Advisory Board, should be presentable to the nation, and he hoped these statistics would form one of the most useful bodies of figures for the hoped-for Ministry of Health. Sir James Galloway described the way in which the National Service medical boards were set up and the careful selection of examiners for the work was made. A very workable scheme of codification had been set up as a result of 12 months' industry, and he distributed among Fellows copies of the schedule in which this was set forth. He spoke also of the work of examination of women in the W.A.A.C. —a less numerous body—under Miss Turnbull, who was assisted by Miss Cameron. A special type of medical man and woman was needed for this work, and those selected had had 12 months of careful training. Consequently, information of vital character was available for 2½ to 3 million people. Concerning many of the results obtained, the Premier's term "appalling" was not in any way too strong, though the results and the proportions of fit men varied very steadily with the kind of occupation followed. Among colliers 72 per cent., 77 per cent., and in one case 81 per cent. were Grade I. men—i.e., men of military age. In contrast to these gratifying figures, cotton weavers yielded 19·6 per cent. Grade I., while Grades III. and IV. amounted to 58·2 per cent. of the whole. In view of the unexpected nature of these figures, a visiting commissioner was sent down, and he reported that the grading carried out by the Board was, in general, correct. Of one day's batch of 59 men only three were found to be in fairly good physical condition. The people here were said to be hard-working and industrious from an early age; they had no time for games, and were content to be earning good money. Tuberculosis, rheumatism, and valvular disease of the heart were very rife. The people worked in a heated and vitiated atmosphere, and on emerging into the outer air easily became subject to bronchial and other troubles. Of 470 examined between two dates 218 were found to have unsuspected tuberculosis. These figures Sir James Galloway further elaborated from his returns. All this surely emphasised the need for carrying on this work of examining and codifying, and he would like to see an examination made of all at about 18 and again when they had had eight or ten years' experience of their life's work. He hoped the medical profession would do their best to make this effort a success.

Mr. D'ARCY POWER spoke of the ease with which thorough examinations could be made. The Special Appeal Board on which he sat was able to make difficult examinations in eight to ten minutes. No provision was made in Sir James Galloway's schedule for mental conditions, but perhaps that would be provided for.

Professor F. W. MOTT spoke of his work on the mental side. He was surprised to find among the inhabitants of a large asylum that 3·5 per cent. were so closely related as parent and offspring, brothers and sisters. One-seventh of the discharged men from the Army were released because of psychoses or neuroses.

Sir ROBERT ARMSTRONG-JONES spoke of the great importance of drill in young life, as shown by the remarkable fitness of the inmates of Dr. Barnardo's Homes.

Dr. E. C. MORLAND, referring to the suggestion that two or three generations of industrialisation damaged the germ cell, asked whether Professor Adami considered such damage to be permanent or was it redeemable.

Sir STCLAIR THOMSON also commented on the importance of the work, of which the medical profession had long been well aware.

Professor ADAMI replied.

LONDON ASSOCIATION OF MEDICAL WOMEN.—The meeting adjourned from Nov. 5th was continued on Nov. 19th.—After a resolution had been unanimously passed that Regulation 40 D of D.O.R.A. was useless for the purpose of diminishing venereal diseases, constructive proposals were discussed, having as their object the arrest of the present widespread increase of these diseases. The proposals included: regulations for keeping the public thoroughfares free from solicitation by either sex and the knowing transmission of venereal diseases, the raising of the age of consent, the registration of lodgings for young people, compulsory secondary technical education for young people under 18. The punishment of brothel-keepers by imprisonment without option of fine, the provision of adequate numbers of women police and the presence of women in police-courts when cases concerning women and children were being taken were also strongly urged. The conclusions reached by the association are being sent to the general meeting of the Medical Women's Federation.

Reviews and Notices of Books.

Emergency Surgery. By JOHN W. SLUSS, A.M., M.D., F.A.C.S., Associate Professor of Surgery, Indiana University School of Medicine; ex-Superintendent, Indianopolis City Hospital; Surgeon to the City Hospital. Fourth edition. London: William Heinemann. (Rebman, Ltd.) Pp. 848. 17*s.* 6*d.* net.

A BOOK on Emergency Surgery may attempt either to include an account of all surgery of an urgent nature, or to limit itself to such of the emergencies of surgical practice as may reasonably be undertaken by the general practitioner. Can it be doubted that the latter is the more useful intention, as it will be the easier of accomplishment? For such a volume is essentially one for the use of the general practitioner, the circumstances of whose work may necessitate his undertaking at short notice, and perhaps far from expert assistance, operative or other treatment which, but for the urgency of the case, he would be glad to leave to others. If, on the other hand, the author is to concern himself with every surgical emergency his book will be loaded and its more important parts obscured by descriptions of cases so rare that no practitioner may expect to meet with them, or of operations so intrinsically difficult that the danger of inexpert performance of them may be actually greater than the risk incurred in waiting for the arrival of one whose training and experience in general surgery fit him for the treatment of such cases.

In our opinion the volume under consideration falls short of success by attempting to be too comprehensive; its author clearly stated, in the preface to the first edition, that "this is surgery for the general practitioner," and so little knowledge is assumed that even a method of making an incision is described and figured, and some of the most ordinary bandages are shown (though we see no reference to the useful many-tail). But, on the other hand, we find accounts and figures of operations so difficult as exposure and suture of the heart and as cervical œsophagotomy, and of such magnitude as amputation at the hip-joint; or, again, of so little urgency as wiring of the patella. Yet there are

omissions, and the reader will search in vain for guidance in a case of perforation of a gastric or duodenal ulcer. While much of the matter is admirably sound and sufficiently lucid, much, again, is too superficially dealt with to be very helpful. Considerable attention has been devoted to the section on military surgery. The book is profusely and for the most part well illustrated, but gains nothing from the inclusion of the coloured figures 420 and 432.

A Preliminary Course of Surgery. By R. L. SPITTEL, F.R.C.S. Eng., Surgeon to the General Hospital, Colombo; Lecturer on Operative Surgery, Ceylon Medical College. With 111 figures in the text. London: Butterworth and Co. 1918. Pp. 466. Rs. 6.6.

THIS book is intended to set forth for the student the first principles of surgery, and to be an introduction to the subject for those beginning their studies. Its author hopes, however, that, as almost the entire field of general surgery has been covered, it will serve as a text-book of surgery for that class of student in India and Ceylon whose limited years of apprenticeship preclude him from the study of larger works. This hope, we think, is too ambitious for fulfilment by the book in its present form; no reasonable limitation of a student's years of study, even though the standard aimed at be not a very high one, should prevent his acquaintance with larger works than this. For the representation of the principles of surgery in this volume is too superficial to be either clear or interesting, while the development of those principles in the later chapters form little more than a collection of lecture notes.

The Practical Medicine Series. Comprising Eight Volumes on the Year's Progress in Medicine and Surgery. Vol. II.: *General Surgery.* Series 1918. Edited by ALBERT J. OCHSNER, M.D., F.R.M.S., LL.D., F.A.C.S.; Major, U.S.M.R.C.; Surgeon-in-Chief, Augustana and St. Mary's of Nazareth Hospitals; Professor of Surgery in the Medical Department of the State University of Illinois. Chicago: The Year-Book Publishers. Pp. 627. $2.50.

THIS volume contains a comprehensive review of the literature on general surgery for the year 1917. The publishers call attention to the fact that although the series is intended primarily for the general practitioner, yet the arrangement in several volumes enables those interested in special subjects to buy only the parts they want. And this volume is well worth buying, either by the general practitioner or by the professed surgeon, for few, especially in these busy times, are so well up in surgical literature as to have no need of such a résumé as this.

We have said that the book is comprehensive; in addition to that it is excellently arranged, with a good table of contents and an index; it is of convenient size, well got up, and with no less than 231 reproductions of figures and 49 plates. The volume is cheap at the price and is cordially to be recommended.

Simple Experimental Hygiene, Physiology, and Infant Management for the Use of School Teachers. By K. M. CURWEN. London: Charles Griffin and Company, Ltd. 1918. Pp. 352. 6*s*.

Miss Curwen possesses varied qualifications as a teacher; she was at one time headmistress of a provincial girls' school in Egypt, and has also been a lecturer in hygiene for the West Riding Education Committee, Her book admirably serves the purpose for which it is intended—namely, to assist teachers to make their hygiene lessons appeal forcibly to their pupils. Dr. G. W. Reid, who contributes a preface, tells us that Miss Curwen was one of the pioneers in the movement for making hygiene a live subject in elementary schools. The book is divided into five parts dealing with (1) the body, (2) food and clothing, (3) the house, (4) vaccination and the prevention of consumption, (5) the care of infants, and an appendix gives some practical hints for laboratory technique. A large number of line drawings illustrate the text, and here we believe that the author would be well advised to obtain a collaborator who will in a future edition make the pictorial part of the book as practical and up to date as the letterpress. We find specially helpful the description of apparatus required at the beginning of each chapter and the blackboard summary at the end. Into a book covering so much ground it is inevitable for a few questionable statements to slip. The infant mortality-rate is now, thank Heaven, not "160 to 170." We do not know what is the "wrong kind of sugar" in tinned milks. The child of 12 months age would, we feel sure, be better for some "hard food." And one or two names are wrongly spelled. But the whole book gives evidence of great care and accuracy, and we can cordially recommend it to school teachers, whether elementary or higher.

Applied Anatomy: The Construction of the Human Body considered in Relation to its Functions, Diseases, and Injuries. By GWILYM G. DAVIS, Pennsylvania. Fifth edition. London and Philadelphia: J. B. Lippincott Company. 1918. Pp. 630. 30*s*.

THE object of this work is to show the relation of structure to function, whether it is normal function or function disturbed or impaired by injury or disease. The present-day medical student is greedy of the practical application of his theoretical studies, and Dr. Davis's book satisfies this praiseworthy greed in complete fashion. The errors and omissions in the book when it first appeared have been more than made good in the later editions, and we can cordially recommend the work to medical students who wish to vivify their anatomical studies, and to practitioners for the purpose of recalling a sound anatomical basis for their practical deductions.

A Junior Course of Practical Zoology. By the late A. MILNES MARSHALL and the late C. HERBERT HURST. Eighth edition. Revised by F. W. GAMBLE, D.Sc., F.R.S. London: John Murray. 1918. Pp. 515. 12*s*. 6*d*.

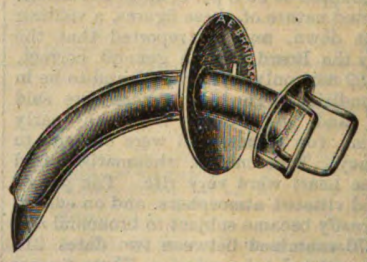
ALL Manchester medical students and many others were brought up on "Marshall and Hurst," and the book in Professor Gamble's hands meets their need now as completely as did the first edition 32 years ago. The war has even introduced a little romance into the study of biology by stopping the usual supplies of material, and Professor Gamble has found, as might have been expected, that the study of unhackneyed types has a stimulating influence on learners and teachers. For instance, the fluke to be found in the frog's intestine now replaces the liver fluke.

The book is an admirable introduction to the study of zoology; whether an elaborate study of selected types is precisely the kind of introductory biological course for medical study is another matter.

New Inventions.

A NEW LARYNGOTOME AND TRACHEOTOME.

THIS instrument is a modification of Fuller's bivalve tracheotomy tube. One valve made of the hardest steel is rendered 5/16 of an inch longer than the other and the concave edge of this prolongation is ground to form a "scalpel-edge." All the remaining borders are rounded off in the usual way. The tip of the smaller valve is made to fit accurately into the groove of the larger valve of the instrument. The inner tube projects slightly beyond the outer, which then lies in close apposition to it, so that, with the inner tube in place, the "scalpel-edge" is thrown completely out of action. The object of the instrument is to do away with the interval between the tracheal or laryngeal incision and the insertion of the tube, thus rendering the operation far more rapid, and consequently less dangerous to the patient. It prepares and accurately fits its own incision, thus allowing no escape of air or blood, and no ill-effects have been found to follow its use.



The laryngotome is made by Messrs. A. E. Braid and Co., Ltd., Gower-place, London, W.C.

A. LAWRENCE ABEL, M.B. Lond.,
Temporary Surgeon, R.N.

FRENCH SUPPLEMENT TO THE LANCET

Under the Editorial Direction of

Professor CHARLES ACHARD, PROFESSOR OF PATHOLOGY AND THERAPEUTICS IN THE UNIVERSITY OF PARIS.

AND

Dr. CHARLES FLANDIN, D.S.O., MÉDECIN-MAJOR DE 2ME CLASSE; CHEF DE CLINIQUE À LA FACULTÉ DE PARIS.

GENERAL REVIEW OF FRENCH CARDIO-PATHOLOGY DURING THE WAR.

By CH. LAUBRY,

PHYSICIAN OF THE HÔPITAUX DE PARIS; MÉDECIN MAJOR OF THE SECOND CLASS.

IN considering the abundant output of French works on cardiac pathology during the past four years the preponderant influence of the war must be recognised. The war has disturbed the heart by its fatigues and emotions; it has created various lesions on a vast scale by the epidemic infectious diseases which it has engendered; and, lastly, by its duration and its consumption of effectives it has rendered daily more urgent the question of the functional aptitude of the heart in terms of aptitude for military service. It is owing to the war that methods of investigation have been revised and established, and new ideas have been acquired on the prognosis of valvular and arrhythmic affections.

Overshadowed by this actual war pathology, whose chapters, inevitably arbitrary, would thus have treated of general symptomatology, organic cardiopathy, acquired or infectious, and functional disturbances, research less concerned with the pre-occupations of the moment has continued without a break. The essentials of this research will not be lost sight of, but only a brief allusion will be made thereto.

Diagnosis of Murmurs.

Search for an indisputable objective sign of a cardiac lesion should first be made by means of clinical examination, and especially by auscultation. This method seems somewhat discredited among certain of our colleagues abroad by reason of its disappointments and of the difficulties of diagnosing certain murmurs, which appear insurmountable. To avoid overcoming these difficulties it is alleged that it imports less to know the significance of a murmur than the functional capacity of the heart which produces it. Indeed, the existence of an inorganic murmur does not, as Josué has well said,[1] inevitably indicate unfitness for military service, but every case of organic murmur should be exempted from active service. We hold that, with certain experience and adhering to the principles to which Potain devoted minute study, it is nearly always possible to establish this capital distinction. I have attempted to render it accessible and practicable[2] by showing, firstly, that the important character of a murmur is indicated by the moment of its appearance in the cardiac cycle. If it is diastolic, no matter where its situation, it is always organic and betrays aortic insufficiency. Trémolières[3] thought that the situation of the diastolic murmur varied with the age of the lesion; it should have its maximum at the second right intercostal space when the lesion is old, and is accompanied by dilatation of the right cavities; it would be to the left of the sternum or mediosternal when only the left ventricle is hypertrophic. In reality the variability of this murmur is such that it appears to me to escape classification; it is sufficient to recognise it in order to avoid an error of diagnosis without seeking for the reason.

Systolic murmurs have two important characteristics, the time of their appearance and their locality; if they are holo-systolic—i.e., prolonged and heard in the whole systole—they are certainly of an organic nature; if they are situated at the base and are not followed by a diastolic murmur they are inorganic. I have ventured to differ from the opinion of Aubertin,[4] who attributed the very frequent isolated systolic murmurs of the base to aortitis in course of development. With regard to this point, it is necessary to distinguish between proto-, meso-, and tele-systolic murmurs, the last two being easily recognisable and always extra-cardiac, the first alone bearing on the discussion in exceptional cases—for instance, of cardiac acceleration. It is especially on their account that attempts have been made to modify the conditions of the occurrence of the murmur.

P. Emile Weill[5] has succeeded, by reducing the cardiac rhythm by ocular compression, in causing inorganic murmurs to disappear, which suggests a diagnostic procedure which would be simple, but is, unfortunately, not infallible. In seeking to apply it I have noticed with Harvier[6] that ocular compression modified, not only the rhythm, but also the energy of the cardiac contraction, and, consequently, certain abnormal bruits (*souffles et roulements*) of organic origin. But in these latter effects, as in its well-established manifestations, the oculo-cardiac reflex is inconstant, varying with each individual,[7] and is capable only of furnishing contingent, and not absolute, data.

The diagnosis of a murmur is almost always possible by means of its intrinsic characteristics, and it should precede other methods. The latter are no less useful, and among them radioscopy should rank first.

Radioscopy.

In their classic treatise[8] Vaquez and Bordet have already formulated the rules of the orthodiagraphic investigation of the heart and the aorta, which furnishes exact indications of the cavities in form, volume and significance, and renders control thereof obligatory in every question of fitness. Beaujard[9] has emphasised its utility in an important memoir, in which he gives a series of measurements of the ventricles, describing, with Caillods,[10] certain forms of isolated left or right hypertrophy, designating the latter "transverse heart." It is owing to radioscopy that Vaquez and Donzelot[11] were able to criticise the regrettable facility with which a soldier was said to have idiopathic cardiac hypertrophy, often said to be developmental. Very often, on the contrary, among young individuals with elongated thorax the heart is small and vertical. Vaquez and Bordet[12] have furnished a new factor, suggested by the method of localisation of projectiles—appreciation of the volume of the left ventricle, which they designate index of depth. By means of other research work they have collected these new data in the second edition of their treatise recently completed.

Arterial Tension.

The measurement of arterial tension should be the usual complement of every cardiac examination. It is practised in France with the aid of the apparatus of Vaquez and of Pachon, each constructed on a different principle. The former estimates by means of palpation of the radial artery the disappearance of the beats of the brachial artery by a counter-pressure equal to the maximum tension; the latter registers and amplifies the oscillations obtained by compression of the artery, the feeblest indicating systolic tension, the strongest diastolic. Without disparaging the excellent apparatus of Pachon, the sensitiveness of which is often deceptive for the evaluation of systolic tension, I have attempted to popularise the auscultatory method, the advantages and precision of which have been shown by Tissier (of Nevers)[13] in a series of technical articles. I have therefore adapted to Vaquez's apparatus a fixed instrument, a sort of stethoscope of resonance, by which can be noted the phases of the superjacent pressure and the data of auscultation and palpation combined. Marfan and Dorlencourt in their memoir,[14] notwithstanding their predilection for Potain's sphygmomanometer, have acknowledged the advantages of my apparatus.

The problem of graphic registration of arterial tension demands no less attention. Barré and Strohl[15] have endeavoured to find an elegant solution without adapting it to the exigencies of current practice. The auscultatory method continues to be preferred, whether my routine is adopted or whether, as Cottet desires,[16] it is limited to the binauricular stethoscope. It may and should be controlled, particularly for the measurement of diastolic pressure, by the employment of Pachon's oscillometer. The latter offers the further advantage of giving, by means of the degree of oscillations and the possibility of applying it to various limbs and segments of limbs, indications of local circulatory disturbances, of the comparative pressure of the various arteries (Cawadias[17]), and of the measurement of tension in the lower limbs, which no other apparatus can give. Heitz has employed it with success for the following purpose: to establish the average diastolic pressure in the lower limbs among normal individuals[18] and to show that in case of aortic

insufficiency, even when diastolic pressure remains invariable, relative systolic hypertension is the rule.[19] This technique has permitted him, with Babinski, to pursue his research on circulatory disturbances in paralysis of a reflex nature.[20]

Arrhythmia.

The graphic method should be reserved for the study of arrhythmia. It is regrettable that we cannot employ an apparatus as ingenious, portable, and practical as that of Mackenzie, the readings of which are practically sufficient. We remain faithful to Marey's polygraph, which has at once the precision and the faults of a laboratory apparatus. The excellent instrument recently designed by Mougeot,[21] with rectilineal tracing, may be substituted for it with advantage. The precise measurements of tracings which it is possible to obtain by means of a sliding-rule have furnished Mougeot and me[22] with information, as faithful as that of an electro-cardiogram, on cardiac energy, on the nature of extrasystoles or of bradycardia, and on the existence of scarcely perceptible alternations.

Functional Tests.

The defaults of methods of investigation has brought back into favour a series of tests the inexactitude of which was long ago pointed out by Merklen[23] and Vaquez,[24] based on modifications in the state of the pulse and arterial tension provoked by effort. Martinet,[25] Lian,[26] and Aubertin,[27] after a course of work agreed upon, drew up the curves of the acceleration of the pulse, of hypertension, and of return to the normal, the slowness of which would be the objective criterion (at once safe and simple) of the insufficiency of the heart and of the circulation in reserve energy.

Vaquez and Donzelot,[28] to whom military fitness as concerns the heart is determined from the combination of facts, do not share this enthusiasm. Lidy and the present writer,[29] in applying these tests to normal subjects and to others suffering from various heart affections, have observed contradictory and paradoxical results which have caused me to accept it with reserve. Tachycardia and arterial tension result from conditions too numerous to draw from their variations an absolute conclusion on the functional capacity of the heart. Vaquez and Donzelot add judiciously that one could do so were it not that information merely relating to insufficiency of the left ventricle cannot furnish an indication of cardiac insufficiency. These authors, though less eclectic than ourselves, like us, accord a certain value to functional tests on condition that they are interpreted in the light of a comparison with other factors. In a concise critical study Esmein[30] justly points out that they have reference to a limited and special effort. The results are inevitably inferior to those that our English colleagues obtain in their training centres and those that a wise medical man may observe in a field of manœuvres or in a barrack yard.

Brachycardia and Tachycardia.

In diagnosis of brachycardia, for the graphic method should be substituted the atropine test or amyl nitrite (Josué), injection of the former or inhalation of the latter producing acceleration of the heart in the case of brachycardia of nervous or sinus origin. Frédéricq criticises these methods in favour of experimental tests.[31] Josué and Belloir,[32] while recognising the justice of his line of argument, nevertheless maintain that a positive reaction to amyl nitrite indicates the excitation of a wave, that it results in total brachycardia, or in exceptional cases of dissociation, and that a negative reaction is proof of a lesional or toxic myocarditic brachycardia. More recently Loeper[33] used the vaso-constrictive properties of adrenalin, measuring the degree of cardiac resistance by the modifications of volume, registered by an orthodiagram, which followed upon a subcutaneous injection, and Mougeot has made attempts in the case of tachycardia with moderating injections of eserine, which promise well.[34]

Organic Cardiopathy in relation to Military Service.

The war has confirmed in an astonishing manner the fact of the remarkable tolerance of organic cardiopathy in regard to excessive fatigue. Aubertin[35] first drew attention to this in the matter of aortic insufficiency and has since confirmed it in cases of all varieties of chronic endocarditis.[36] Doctors who have been able in their hospitals at the front or at home to bring together a number of cardiac cases have drawn up suggestive statistics in this connexion (P. E. Weill,[37] Etienne,[38] Ch. Laubry[39]).

In spite of the conclusions to be drawn therefrom, which are all the more reassuring because dealing with aortic or congenital affections (Grenet,[40] Augé and Nobécourt,[41] Ch. Laubry and Marre[42]), it would appear that the authors agree in omitting to study the bearing, and in neglecting the existence of a valvular lesion in estimating fitness for military service.

As a sequel to the recent communications of Lafosse,[43] Clerc and Aymé,[44] and Gouget,[45] a discussion took place at the Société Médicale des Hôpitaux, and all agreed in excluding cases of valvular affection of the heart from active service; but some, judging by experience and allowing for certain conditions of adaptation, advise for heart cases modified auxiliary service; others, having regard to the difficulties of a rational method of recruiting these cases, request that they should be discharged.

The gravity of a valvular lesion at the front lies less in the cardiac miopragia, which is often nil or negligible, than in the vulnerability of a case of endocarditis to rheumatismal relapse, and also to all kinds of infectious attacks. One heart, the lesion in which has been definitely determined, will behave like the normal; with another, apparently less acutely affected, progressive palpitation, whether obvious or insidious, warrants a grave prognosis.

Relation between Injections and Cardiac Lesions.

In connexion with their genesis acute articular rheumatism is of the first importance, inasmuch as it has grave effects in an endemic condition, and is prevalent in trench warfare. Sometimes its onslaught is evident, at others it is masked by manifestations whose rheumatismal nature is less apparent—e.g., angina, gastric derangment—while yet at other times cardiopathy alone exists or develops, affected by salicylate (Josué, Parturier, and Berrut[46]). One of the predisposing forms, according to Nobécourt and Peyre,[47] is cervical rheumatism associated with sciatic neuralgia, in the course of which almost invariably an augmentation of volume by dilatation of the heart is discernible, either isolated or accompanied by endocarditis or acute endo-pericarditis.[48]

Scarlatina does not spare the heart, and its cardiac manifestations are as frequent among the military as among children. They may supervene in the course of a rheumatismal complication (Nobécourt, Jurie des Camiers, and Tournier,[49] Nobécourt and Gimbert,[50] Florand and Merklen[51]), or they may appear at the outset (Nobécourt,[52] Florand and Paraf,[53] de Massary[54]). They are marked by abnormal and persistent acceleration of the pulse (Nobécourt and Gimbert[55]), by endocarditis, especially mitral, occasionally by pericarditis, with the myocardiac syndrome uncertain.

The epidemics of typhoid fever which raged at the beginning of the war have confirmed the gravity and the persistence of cardiac disturbances which are frequent sequelæ thereof.[56] They similarly accompany complications of paratyphoid, but in this case are more benign and superficial, being limited at the acute stage to feebleness and inequality of the pulse and dullness of the sounds, with embryocardia (Minet[57]), rarely deep-seated, accompanied with phlebitis (Nobécourt and Peyre,[58] Parisot and Orticoni,[59] Etienne[60]). The grouping of these cardio-vascular lesions is the subject of a notable memoir by Carles and Marcland.[61]

In typhus, on the other hand, severe cardiac symptoms are the rule and myocardiac insufficiency and arrhythmia of unfavourable import. We owe to Danielopol a complete account of them, with successful attempts at treatment with strophanthin and adrenalin.[62]

Finally, mention must be made of infectious endocarditis. One form of this, which is less known in France and to which Osler in England had the distinction of drawing attention—the subacute or chronic form—has been the subject of numerous publications. Debré,[63] Denéchau and Picard,[64] Fayolle,[65] Roger,[66] have observed cases which they have studied from a clinical, anatomical, and bacteriological point of view, of which Debré gives a general summary.[67] Achard and Foix[68] have emphasised the anæmic form, Claude[69] the nervous form, of the affection. Lastly, Vaquez,[70] by means of copious valuable documentary evidence and statistics of 17 cases, brings into prominence the fatal prognosis at the expiration of a period varying from 4–14 months and two years. During the war the relation between infection and cardiac lesions, especially valvular, has been established and confirmed.

Effect of Traumatisms.

Traumatisms, in spite of their frequency and their violence, play only a negligible part in the etiology of heart disease. As a result of violent disturbance aortic insufficiency may be seen to develop (Bensaude,[71] Alex. Cramer,[72] Brossard and Heitz,[73]), but these cases, which seem *bona fide*, are excep-

tional. The question may always be asked, in the absence of necropsic findings, whether the traumatism has acted by damaging the tissues or by encouraging a latent infection, as in traumatic aneurysms or syphilis is nearly always the case. In this sense traumatic pericarditis without tissue damage has been mentioned[74]; the accuracy of this view is doubtful.

Functional Disturbances.

Acute diseases may not only create grave and distinct cardiac lesions, valvular or otherwise, but especially may cause a series of functional disturbances which will increase or diminish according as the soldier is exposed anew to the fatigues of the military life or is exempted from them. He enters in that case into the huge group of cases of palpitation or tachycardia through the gateway of infection. But that is far from being the only way of access. Sometimes it is a case of over-exertion and of an actually over-worked heart; at others the organ, affected by a violent disturbance, becomes henceforth continuously tachycardiac (Dejerine and Gascuel,[75] Laignel-Lavastine,[76] Charon and Halberstadt[77]); again, the action of asphyxiating gases may be in question (Heitz,[78] Lian[79]); while yet again, emotions whose repetition may act as a substitute for acuteness may produce progressively a condition which the emotion produced at the outset.[80]

The war has by no means created this category of patients in its entirety, as Gallavardin has justly remarked.[81] It has often merely revealed them. In time of peace these cases existed, but the subjects adapted themselves to their hearts; they adjusted their efforts and occupations to their functional capacity and thus experienced no need to have recourse to medical aid. We considered them as emotional and unstable folk; we recognised willingly the sincerity of their sufferings. But in the absence of any objective symptom we supplied a favourable prognosis and gave them as sole treatment congenial and comforting assurances. The new and onerous obligations of military life have literally encumbered the hospitals with these types of neglected cases, and on account of their frequency it has been urged that they should no longer be viewed with scepticism. In England they have called forth discussions and been the object of an authoritative report by Dr. Thomas Lewis (see THE LANCET, 1917, i., 580).

In France, too, there have been attentive observers to whom the only reproach that can be addressed is that they have not coördinated their efforts or classified their conclusions. One may recall the works of Martinet,[82] Lian,[83] Aubertin,[84] Clerc and Aymé,[85] and especially the critical review of Gallavardin,[86] in which the eminent cardiologist of Lyons does not merely analyse in detail the work of Lewis, but also furnishes a personal study, a model of brevity and modesty. Arterial hypertension appeared to Gallavardin to occur more frequently than Lewis had suggested, a view with which Aubertin agrees,[87] as also Du Castel[88] and especially Merklen,[89] who makes of it the characteristic of the syndrome and a factor in classification. It is, in fact, a contingent symptom which we have never been able to distinguish clearly, and which appears to us fleeting, transient, and often as unstable as the heart itself. When it exists it is systolic tension alone which is the cause, for we refuse to admit to this group, as Merklen does, the cases of minimum tension remaining raised in a perceptible and permanent manner. It is a question from that time of true hypertension, from varying causes, which has become tachycardiac.[90]

Diagnosis of Disturbances of Function.

It is necessary to obtain for each patient, as Gallavardin advises, with minuteness and patience a series of curves which will demonstrate the manner of the rhythm, normal curve, curve of situation, nycthemeral curve, and even the curve of emotivity. By means of this analytical study, somewhat opposed to the synthetic study, the problem of aptitude is solved, not mathematically, but clinically, in accordance with Lewis's recommendations. By making use, as I did in the hospital of Professor Vaquez, with the coöperation of my collaborators, Esmein, Mougeot, and Bordet, of a thorough clinical and radioscopic examination of the heart, by hunting out thus the cases of slight endocarditis, incipient valvular lesions, isolated dilatations of the cardiac cavities, myocarditis in course of development, which in cases over 40 years of age frequently conceals itself under a mask of tachycardia, and by eliminating cases of true and permanent hypertension, we concentrated our attention on a group of pure instabilities whose importance was easily established, and our military decisions are rarely nullified by the subsequent conduct of the subject. Our decisions are also in agreement with the discreet conclusions of Gallavardin, Clerc and Aymé, and Aubertin.[91] We decide upon discharge, auxiliary service, or modified active service either with mounted troops, or in training under surveillance, according to the gravity or persistence of the tachycardia, or to the degree of instability which is either calmed definitely by rest or in a period of a few seconds changes its rhythm in a disconcerting manner. For each case it is a question of the species of disturbance, and it is the same from the pathogenic standpoint. It must be ascertained whether the disturbances of function arise from an infection, from slight myocarditis (Lian[92]), from toxæmia, or from nervous loss of equilibrium, either constitutional or acquired, which is itself controlled by a disturbance of the internal secretory glands. In considering merely the polymorphism of the etiological factors, the dissimilar indirect elements of a syndrome, which is only uniform in appearance and of which ultimate research should tend to dissociate the constituents, the divergence of authors and the impossibility of adopting a uniform theory become comprehensible.

Tachycardia is not the only form of cardiac instability that concerns the soldier. On the other hand, arising from the same origins, but not on so vast a scale, is brachycardia analogous to the brachycardia of convalescence. It should end in recovery after a sufficiently long period of time (Binet,[93] Gouget,[94] Hirtz[95]). Several forms of this, as we have observed with Esmein,[96] are the expression of a total and persistent atrio-ventricular dissociation.

Progress of Current French Work on Cardiac Pathology.

The advance in cardiology brought about by the war, of which we have attempted to sketch the amplitude in outline, has but momentarily and feebly disturbed the normal current of French work on cardiac pathology. After a stationary period brought about by events there have appeared memoirs on the vexed questions of the physiology of the heart, its functional localisations, and the pathogenesis of certain forms of arrhythmia, as well as of others more exclusively clinical or therapeutic, and of others in which the mechanical point of view is abandoned for the humoral. It concerns us less here to analyse them than to allude to them briefly.

Petzetakis has studied the effect of the section of the cervical marrow on the rhythm,[97] and, pursuing his observations of arrhythmia, has demonstrated the possibility of an inverse cardiac conductibility with retrograde extrasystoles and post-extrasystolic ventricular automatism.[98] Pezzi,[99] by registering graphically the effects of ocular compression, has remarked the production of extrasystoles, thus contributing to the elucidation of the mechanism of the latter, which the experimental research of Pletnew has since crystallised.[100] We owe, further, to Pezzi's work a new interpretation of the gallop rhythm and the rolling sound of Flint—viz., aortic insufficiency—which he attributes, on the evidence of the tracings, to auricular hypertrophy. I will pass over the numerous irregularities which occupy so much space in the periodicals, while mentioning the form of cardiac inversion reported by Clerc[101] in a discourse on pathogenesis and embryology, which exhibited the peculiarity of not being accompanied by visceral transposition.

The variations of azotæmia among cardiac cases may arise from simple oliguria or from defective functioning of the kidney or liver. Josué and Parturier,[102] for instance, have described an azotæmia from oliguria without affection of the kidney, a renal azotæmia, as well as azotæmia from relative oliguria among cardio-renal cases and also among cardio-hepatic cases oliguria without azotæmia. The first naturally subsides under the influence of digitalis.[103]

Ch. Achard and Leblanc,[104] who have given attention to the same phenomena, assign a rôle to the variations of renal concentration, the stasis when prolonged diminishing temporarily the concentrating power of the kidney.

In conclusion, Vaquez, in elaborating his treatise on "Diseases of the Heart," adds to his records the most original chapters on his conception of angina pectoris,[105] on the symptoms of resorption of an œdema,[106] in which he traces the effect of phenomena, not merely mechanical but also toxic, analogous to anaphylactic shock, and has recently produced his "Introduction to the Study of Diseases of the Heart."[107]

This documented review of the men and methods which have gradually transformed cardiac pathology could not be better concluded than by recalling the new therapeutic methods of Vaquez. For the efficacious but dangerous

intravenous injections of strophanthin Vaquez has substituted Arnaud's injections of "onabaine," extract of strophanthus kombe, and has made from it an active medicament, not destined to supplant digitalis, but having, along with it, its proper indications, represented by a rational appreciation of the insufficiency which it is intended to combat, and which is more especially insufficiency of the left heart.[108]

METHODS OF ESTIMATING AUGMENTATION IN DEPTH OF VOLUME OF LEFT VENTRICLE.

By Dr. Bordet,

DIRECTOR OF THE RADIOLOGICAL LABORATORY OF THE CENTRE OF CARDIOLOGY OF PROFESSOR VAQUEZ, HÔPITAL ST. ANTOINE.

If it is usually easy to determine by percussion the area of cardiac dullness and to estimate the degree of augmentation of the left ventricle in cases of considerable hypertrophy of this cavity, it is often impossible to obtain by clinical means a satisfactory estimation of the volume of the heart when it has only suffered slight modifications. Radiological methods of precision—i.e., radiography at a distance of three metres—and orthodiagraphy are the only means of obtaining information of great exactitude.

The augmentation of the longitudinal diameter of the cardiac area, the lengthening of the left margin and the accentuation of its convexity, the globular appearance of the point and its depression constitute objective signs of left ventricular hypertrophy. These signs may always be insufficiently characterised, and may occasionally be lacking when there does, in fact, exist a certain degree of hypertrophy. If, therefore, it escapes radiological investigation it is because it is not sought in the part of the organ where it manifests itself anatomically. The anterior or posterior view of the cardiac shadow indicates the dimensions of the heart in a longitudinal and transversal direction; it does not reveal its development at all in an antero-posterior direction. Thus, if it is taken into account that the left ventricle occupies but a narrow strip of the left margin and that it is situated almost entirely on the posterior portion of the organ, the conclusion suggests itself that it is in depth that this cavity develops when it becomes augmented in volume. Every method, therefore, which has for its aim the determination of the variations in volume of the left ventricle, in the direction of its principal development, will lead to the recognition of cardiac hypertrophy as early as possible after its commencement. Professor Vaquez and I[1] make use of the two following radioscopic methods:—

1. *Estimation of the angle of the disappearance of the apex of the heart in the right posterior oblique position.*—In examining an individual on the screen, placed in the dorsal position, if the body is made to describe a rotatory movement from right to left the pictures of the heart and the vertebral column travel in an inverse direction; the former is displaced towards the right, the latter towards the left, and a moment arrives when the external profile of the apical zone before disappearing becomes level with the spinal apophyses. The angle at which the shadow of the apical zone disappears increases with the extent of the globular condition of the apex of the heart and its development in depth.

To calculate this angle a goniometer is used, which gives the degree of obliqueness of the bi-scapular line with the margin of the screen. Multiple observations have led us to the conclusion that the angle of disappearance in normal individuals is 25-30°. Beyond 30° authorises the conclusion that there is an augmentation of the ventricular volume.

2. *Ascertaining the index of depth.*—This method does not require the use of any special measuring apparatus. The patient to be examined is placed in the direct anterior position, the region of the sternum in contact with the screen. The normal projection of the apical zone of the heart and its deformation by an oblique ray resulting from the lateral displacement of the tube over a fixed distance are marked off successively. It is a method well known to radiologists for the locating of foreign bodies. The conditions necessary for the experiment are obtained by a fixed screen placed at a certain distance from the tube. The greater the depth of the ventricular development the sooner will the oblique ray meet the posterior contour of the heart and the further from the normal point will its projection be. The distance between the two points of projection, marked on the screen by a pencil, constitutes the index of depth. It varies among normal adults from 7-14 mm., the screen being at 60 cm. from the focus and the displacement of the tube 10 cm. Beyond 14 mm. the development of the depth of the left ventricle is exaggerated. In cases of acute hypertrophy it reaches 20, 25, or 30 mm.

These two methods give analogous indications. They exercise mutual control, and recourse should always be had to one at least to complete a volumetric examination of the heart. The measurement of the index, on account of its great rapidity, appears to us a very advantageous method in a military centre of cardiology, where numerous radioscopic examinations must be effected daily.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 30, 1918.

The Antiscorbutic Factor.

WE publish this week a Memorandum on Food and Scurvy issued by the Food (War) Committee of the Royal Society. Comment has already been made in these columns on the practical manner in which the highest scientific authorities in this country have placed their special knowledge at the disposal of the Government, and the Memorandum is one instance of many which show how valuable the services so rendered have been. This document has been based chiefly upon investigations which have been carried out at the Lister Institute, and the statement as to the cause of scurvy has nothing new about it save the definite recognition of the presence in many foods of certain accessory basic substances the exact nature or composition of which remains obscure, but whose benign influence is indubitable. These substances are present in a number of fresh foods and are a special characteristic of oranges, lemons, and fresh green vegetables, though swedes, potatoes, and other roots and tubers contain them; they are present in traces also in fresh meat and milk. They are deficient in all dried and preserved foods, and they are destroyed, we are reminded in the Memorandum, by prolonged heating. It is further pointed out that there is no association between scurvy and tainted food, and that as alkalies destroy antiscorbutic properties soda should not be added to the water used for the cooking of vegetables. The one new observation by the Committee with regard to the cause of scurvy, it will be observed, is an omission and not an assertion; in discussing etiology the word "limes" is absent. This is significant, because the popular view, and one endorsed until lately by the medical profession, has been that lime juice, as ordinarily prepared, is a specific; it is now found to be useless for the prevention of scurvy in the preserved form which it usually takes in the Navy.

Such, at any rate, are the irresistible conclusions of the interesting communication entitled "The Relative Content of Antiscorbutic Principle in Limes and Lemons," which we publish this week, by Dr. HARRIETTE CHICK, Miss E. MARGARET HUME, and Miss RUTH F. SKELTON on the experimental side of the question, Mrs. ALICE HENDERSON SMITH contributing a historical report. The work emanates from the Lister Institute, Director's Department, and is, in fact, the careful and illuminating investigation upon which the Memorandum of the Food (War) Committee of the Royal Society is based. It was found that when the antiscorbutic value of the juice of fresh limes was compared experimentally with that of fresh lemons the former fruit was distinctly inferior. The experiments were made on guinea-pigs and monkeys. Volume for volume fresh lime juice possesses, we are told, a potency of about one-fourth that of lemon juice, and in one instance severe scurvy, which had developed in a monkey on a diet containing a small daily ration of fresh lime juice, was cured by an equal ration of fresh lemon juice. Preserved lime juice was found quite useless for the prevention of scurvy, even when the dose was pushed to the toleration limit. The experiments allow that here the age of the samples might have been held to account for their inefficiency. Experiments still in progress with preserved lemon juice have given promise already of good results.

A reference to the history of the treatment human scurvy completely confirms the experimental findings, and Mrs. HENDERSON SMITH is to be congratulated on a valuable and amusing piece of research. At the period when scurvy was eliminated from the British Navy by the agency of "lime juice" that term was applied to the juice of lemons, and it was not until the second half of the nineteenth century that the juice of West Indian limes was adopted in the Navy and Mercantile Marine. In her historical inquiry Mrs. HENDERSON SMITH quotes the history of two Arctic expeditions—that of the *Investigator* in 1850 and that of the *Alert* and *Discovery* in 1875. The former, supplied with lemon juice, experienced remarkable immunity from scurvy during the first two years of great difficulty and privation; the latter, supplied with lime juice, suffered severely from scurvy at the end of the first winter spent in the Arctic regions. The coöperation of the four authors completely establishes their theses, so exactly does the historical evidence bear out the biological research. And once again we are reminded that man is not a steam engine, though in discussions on diet the comparison is generally convenient. The calorific value of food rightly enough claims first consideration when discussing questions of efficient dietary, but it is clear that the calorie avails nothing without the coöperation of accessory substances. This is where the analogy between the requirements of the human machine and the steam engine breaks down.

The Inheritance of Abnormalities.

DAY by day cripples almost beyond number are leaving hospital or returning from distant prison camps. Some of them are already married men; many of the remainder will have the immediate opportunity of marrying. Doubt has been widely expressed in regard to the effect of such unions on the coming generation. Few, even of the uninformed, think that a wooden leg or a glass eye is handed on to offspring, but ignorance is widely spread in regard to the inheritance of abnormalities, and the present is a suitable time for re-stating our knowledge on the subject. We take as our text the interesting communication which appears on another page from Dr. VOORHOEVE, of Amsterdam, on a pedigree showing hereditary abnormalities of

several kinds—blue sclerotics, brittle bones, hæmophilia, and others. Dr. VOORHOEVE suggests as a tentative hypothesis that all these abnormalities are due to congenital inferiority of the embryonic mesenchyme, leading to abnormal effects of different kinds in the several members of the family. Whether this hypothesis is well-founded or not, the pedigree is undoubtedly of great interest, as showing the manner in which several uncommon congenital defects are transmitted. In recent years much work has been done on the inheritance of congenital abnormality, and the excellent pedigrees collected, for example, by NETTLESHIP in various affections of the eye, DRINKWATER and others in brachydactyly, and those issued under Professor KARL PEARSON'S direction in the "Treasury of Human Inheritance," show that quite a considerable number are inherited according to MENDEL'S law. Those that do so fall into three classes: (1) those in which the defect behaves as a Mendelian dominant; (2) those which are recessive; and (3) those which are "sex-limited" in transmission. A dominant character is transmitted only from an affected parent, and when the other parent is normal the expectation is that it will appear on the average in half the children. Examples of this class are brachydactyly, "split-foot," congenital cataract, retinitis pigmentosa, and a number of other abnormalities are almost certainly transmitted in the same way. In none of these does an unaffected member of an affected family ever transmit the defect. Recessive characters, on the contrary, only appear if the "factor" for the defect is received by the child from both parents. Each parent may thus unwittingly bear the "factor" without showing any trace of it, but if the germ-cells which unite in fertilisation both possess it, the child will show the defect. The best-known example of this class is albinism; others that are said to be transmitted in the same way are some forms of deaf-mutism, hereditary epilepsy, and insanity. Rare affections of this class are liable to appear most commonly in the children of first-cousins, for it is more likely that the factor will be present in both parents if each receives it from a common ancestor. Affections of the third group, showing sex-limited transmission, occur chiefly in males, very rarely in females, and are transmitted from an affected man through his daughters to half their sons. The sons of an affected man are normal and do not transmit; his daughters appear normal, but on the average half their sons are affected and half their daughters are again transmitters. Only if an affected man marries a transmitting woman can the affection appear in a female. The best known examples of this class of hereditary defect are green-red colour-blindness, horizontal nystagmus associated with deficient pigment, night-blindness, and hæmophilia.

In addition to the abnormalities which are certainly or probably inherited, according to MENDEL'S law, there are a number of others, such as, if we are not mistaken, hare-lip and cleft palate, which are undoubtedly hereditary, but which are irregular in their appearance, being sometimes transmitted direct from parent to child, and sometimes appearing in the children of normal persons who belong to affected families. It is not impossible that the explanation of this irregularity is that the character requires for its manifestation the presence of two independent hereditary "factors," neither of which alone is sufficient to produce it. When such a condition exists in animals or plants it is easy by experimental breeding to demonstrate that the coöperation of two factors is required, but when our only means of investigation is limited to the collection of pedigrees the analysis of such examples is fraught with considerable difficulty, and in many instances no definite solution can yet be offered. Only by the collection of carefully verified pedigrees can a complete analysis be hoped for, and for that reason especially we welcome Dr. VOORHOEVE'S contribution. His family illustrates one of these anomalous cases. The blue sclerotic is transmitted sometimes direct from parent to child, but there are two instances in which members of the family recorded as unaffected have affected children. Since the abnormality is mentioned as varying in intensity it is possibly irregularly dominant, or dominant only when some other factor is present in addition. The brittleness of bones is recorded only in persons having blue sclerotics, and is transmitted direct from parent to child, but there are a number of persons with blue sclerotics and no bone-brittleness. Another interesting feature is the manner of occurrence of hæmophilia. This pedigree supplied by Dr. VOORHOEVE resembles the classical examples in showing the disease confined to males, but differs from them in the manner of its transmission. The disease presumably came into the family through the male ancestor, since one of his sister's sons is recorded as being affected, and yet it appears in his sons and is also transmitted through one of his grandsons to a male child. Evidently, therefore, hæmophilia in this family is not transmitted according to the normal rule of sex-limited inheritance in which an affected man never transmits either to, or through, his sons but only through his daughters. Experiments on animals, especially those of T. H. MORGAN on the fly *Drosophila*, have shown that characters which superficially are so alike as to be easily confused, may be inherited quite differently, and from this and other anomalous cases that have been recorded, it seems not improbable that there are at least two forms of hæmophilia, due, perhaps, to different ultimate causes, and differently inherited, but clinically showing similar symptoms. Only the careful collection of pedigrees by qualified observers can elucidate such problems as these. The invitation to further research is pressing.

About the origin of these inherited defects nothing is known. It may be safely asserted that mutilations are never transmitted, and most biologists would say with equal confidence that no effects impressed on the body from without can influence the offsprings. A few keen observers find contradiction here in the depreciation of human stock under industrial conditions. Speaking on Monday evening at the Medical Society of London of the painful impression left on his mind when visiting the industrial centres of northern England after a long absence, Professor J. G. ADAMI went on to say:

> The stunted appearance of the workpeople in spite of apparently abundant food, and of cottages no longer back to back, but in fair sanitary condition, lead to the conclusion that we have to deal, not with a condition of individual acquirement, but with a germinal defect: fathers and mothers engaged day in, day out, at indoor occupations, undergo a slow sapping of their strength and a low form of intoxication which tells on the germ cells as on the body in general, so that the offspring comes into the world in an enfeebled condition and with incomplete endowment of cellular activity.

Experiments like those of STOCKARD on the production of defective descendants from guinea-pigs treated with alcohol also suggest that it may happen that toxic substances circulating in the body will so affect the germ cells as to give rise to abnormalities which reappear, sometimes even intensified, in later generations. But whether such causes as these, or accidental abnormalities in the nuclear division of a germ cell, are responsible for the first appearance of congenital abnormalities is at present entirely beyond our knowledge, and is one of the most pressing problems which biology has to face.

Annotations.

"Ne quid nimis."

UNIVERSITY REPRESENTATION.

IT is clear that there can be no representation of the medical profession in Parliament as a profession, but university constituencies are the ones which, on the one hand, are most likely to send Members to Parliament who understand medical questions in relation to general sociology, and which, on the other hand, offer the best chance to the medical man of election in recognition of his equipment. It appears that there will be contests in all the university constituencies in Great Britain. In the University of London there are four candidates for the single seat—Sir Philip Magnus (Coal. U.), Mr. Sidney Webb (Labour), Mr. A. A. Somerville (Teachers), and Major-General Sir Wilmot Herringham, physician to St. Bartholomew's Hospital and consulting physician to the Forces in France, who declines to label himself as of any party, but who will support the present Government in its efforts to complete the war. For the three seats of the four combined Scottish universities there are seven candidates—Sir Henry Craik and Sir Watson Cheyne, the sitting Members, are again candidates, as well as Dr. P. Macdonald and Mr. T. M. Watson, of the Labour Party, Mr. D. M. Cowen, of the Council of Teachers, and Professor W. R. Smith. There are several medical men who would be willing to stand even at this late hour if constituencies were available, but the lateness of the attempt to organise medical candidatures prevents assistance being rendered, while the candidates for university suffrage have been arranged. The Medical Parliamentary Committee is endeavouring to arrange for a supply of medical speakers to assist candidates as required, and to this end the coöperation of the British Medical Association, the National Medical Union, and the Medico-Political Union has been invited.

THE PROBLEM OF A CLEAN MILK-SUPPLY.

IT has been demonstrated again and again that our milk supplies are collected and delivered under most reprehensible conditions, and yet no serious step has been taken towards reform. But the urgency of the problem has, at all events, received the recognition of the Ministry of Food, which has recommended the Government to take over the wholesale distribution of milk, a proceeding which ought to result in the delivery of a clean supply. The Manchester City Council are contemplating dealing with that city's milk-supply in the same way, and under the instructions of a subcommittee appointed by the sanitary committee of the council Professor S. Delépine has presented a report on two important matters connected with the problem. These are (1) the best method of determining the degree of contamination of samples of milk for administrative purposes; and (2) the actual state of the Manchester milk-supply. Taking the second point first because it can be dismissed in a few words, the results shown by Professor Delépine as regards contamination by dirt of Manchester milk "are deplorable." The contamination progresses from collection to delivery. Seriously contaminated at the stations, the condition of the milk is much worse by the time it gets into the shops and worse still by the time it arrives at the actual consumer. In deciding upon the best administrative procedure for determining the purity of the milk-supply Professor Delépine is led to recommend two methods: (1) the counting of the number of bacteria per c.cm. of milk, which, of course, involves time and the services of a skilled bacteriologist; and (2) an incubation method in which is recorded the time required for the milk to go sour under certain conditions. It is suggested that this latter method, if worked out and standardised, might provide a reliable test as to the purity of the milk, which could be carried out after a short period of training by almost unskilled persons. We believe this to be a valuable suggestion, for in this way the farmer who is anxious to supply a clean article might be furnished with a reliable and comparatively simple test and means of control. Particulars are set out by Professor Delépine as to how and why contamination takes place at the farm, on the railway, at the dealer's shop, and during distribution, and the steps that should be taken to prevent contamination at all points are described. The report, enforced by much painstaking work, presents the results of very careful and extensive scientific investigation.

TREATMENT OF GANGRENE OF THE LUNG BY INDUCTION OF PNEUMOTHORAX.

THE treatment of gangrene of the lung remains disappointing, in spite of much research given to it both on the medical and surgical side. Excision has proved too dangerous even in the most skilful hands. At a recent meeting of the Académie de Médecine of Paris M. P. Émile Weill claimed good results from the induction of pneumothorax. This procedure, which has found an assured place in dealing with caseating lung tissue, is alleged to act on the gangrenous focus by causing its discharge with formation of a cavity, the walls of which subsequently adhere to one another, the patient being cured in a short time. For the practice of this treatment it is necessary, as soon as the diagnosis is made, to examine the affected lung with the X rays, which will show the position of the focus and the condition of the pleura. In one of M. Weill's cases there was a large serous effusion, but usually the pleura contained only a few cubic centimetres of serous or sero-hæmorrhagic fluid. It is then easy to remove the fluid and insufflate under the control of the screen. In the rare cases in which the pleura has not reacted with effusion nitrogen is injected into the potential pleural cavity under manometric control in the same way as for the treatment of pulmonary tuberculosis. If there are pleuritic adhesions the injection would be performed at a point where the lung is not adherent, and it probably would not be difficult to break down fresh adhesions. M. Weill generally found it necessary to renew the pneumothorax after a few days. This is not surprising in view of the fact pointed out in our present issue by Dr. Claude Lillingston that irreparable

harm may be done by too long spacing of the injections, while their frequent repetition appears to be quite free from risk. In pulmonary gangrene when a complete pneumothorax is produced M. Weill finds that the temperature falls, the expectoration dries up, the fœtor of the breath disappears, and a complete cure, functional and anatomical, which may be followed on the screen, is brought about in less than a fortnight. Even when other gangrenous processes complicate the pulmonary gangrene temporary improvement results. The temperature then falls for a short time but rises again, in spite of the cessation of the expectoration and fœtor, and the fatal progress is resumed. It is therefore important to diagnose pulmonary gangrene early, and to intervene before complications have transformed a curable into a fatal malady. The method may be assisted by the usual medical treatment. In the case of a man suffering from pulmonary gangrene complete radiographic and clinical cure was produced in 11 days. Pneumothorax was twice induced at an interval of five days. The first operation led to the formation of a cavity with fall of temperature, the second to cessation of expectoration and apyrexia. In another case there were the complications of serous pleurisy and gangrenous pericarditis. The pneumothorax suppressed the pulmonary disease, cicatrisation of which was found beginning at the necropsy, but the cardiac complication was not influenced, and, after a brief improvement, it proved fatal. Gangrene of the lung is fortunately a rare condition, but M. Weill's experience should direct attention to a possibly effective method of dealing with it.

LIGHT AND HEALTH.

IN Switzerland cow-byres are lighted by electricity. Some of the pig-styes are also so lighted, presumably more for the convenience of the caretakers than of the actual inhabitants. In the rural parts of our own country such amenities are not available even for the human population. The horrible darkness of the country is, indeed, the townsman's chief complaint when he is forced to live under rural conditions. Darkness cripples all his activities and reduces him to a partial state of hibernation. The inability of the town-dweller to see in the dark constituted a grave difficulty in the training of troops for trench warfare, where to take prompt advantage of the slightest glimmer of light is a military asset of enormous importance. Possibly the troops now returning home may have learned their lesson so well that darkness will no longer be a serious bar to rural life—possibly, too, the born countryman may scarcely be conscious of the drawback—but since the population is so largely urban we are in entire agreement with Sir H. Rider Haggard, who, in a letter to the *Times* of Nov. 19th, ascribes the desertion of the rural districts in large part to their appalling darkness during the long winter months. If it is technically possible, there seems no conceivable reason why, in fairness to the rural dweller, the village street and the village house should not be as brightly lighted as those of the towns. If it is merely a question of distribution, the problem has long been solved in other countries by the overhead conduction of high-tension current. The plea of danger has been negatived by experience. No Swiss village is without its brilliant electric illumination, while every tenth house has its telephone, by means of which conversation can be carried on with neighbouring valleys which might take 10 or 12 hours to reach by rail or road. But Swiss boys, although no mean climbers of electric standards, are not electrocuted, and even birds perch unscathed. If it is a question of quantity of current and of resulting cost, then the towns might well spare some of their garish brilliancy to the villages. Natural water-power, as everyone knows, answers many questions about cost, but surely we need not stand with folded hands neglecting all things because one natural advantage is denied us. We do not know whether it would be possible to light country highways, but short of this the finger-posts at corners should be made easily readable by night as by day and all dangerous crossings illuminated. Some may hold that these are merely questions of convenience, but the effect of light on health is one that cannot be gainsaid. The winter gloom of day-time in Marylebone and Kensington, in Lancashire manufacturing centres, and on the dockyards of the Clyde must result in a general lowering of vitality which predisposes to disease—we are not referring to the artificial darkness of wartime, but to the climatic amenities of these islands. It is not direct sunlight alone which is beneficial; bright diffused light invigorates even when the sun itself is obscured. The "artificial sun" of the mercury-vapour lamp has been shown to take the place in part of the real orb. Brightly lighted play centres for town children will probably demonstrate the same truth. Something should be done, and done quickly, to remove the day-time gloom of our cities and the night-time gloom of our villages. They constitute one of the greatest impediments to healthy outdoor life in the long winter months. We commend the subject to the consideration of those who are planning central power-stations.

THE MEDICAL INSURANCE AGENCY.

A MEETING of the committee of the Medical Insurance Agency was held at 429, Strand, on Thursday, Nov. 21st, under the chairmanship of Dr. G. E. Haslip. The financial position was found to be quite favourable, the prosperity of the committee having been well maintained in the last year of the war, while promises of future development are sound. The committee decided, having regard to the funds at their disposal, their commitments on the one hand and their impending receipts on the other, that a further distribution of £500 should be made to medical charities. This is the same sum, it will be remembered, as was dealt with in the interim distribution in May of this year, the result being that the Medical Insurance Agency has been able in the fourth year of the war to give £1000 in aid of first-class medical charities while continuing rebates to their clients of a highly satisfactory nature. The second £500 was allocated as follows: Royal Medical Benevolent Fund, £100; Royal Medical Benevolent Fund Guild, £100; Epsom College Benevolent Fund, £100; Royal St. Ann's School, £100; War Emergency Fund, £50; Birmingham Medical Benevolent Society, £25; and the Royal Medical Benevolent Fund of Ireland, £25. As a result of this distribution the total of sums allocated to medical charities has reached £4405. In the course of the meeting the chairman stated the position that had arisen between two medical charities—the Royal Medical Benevolent Fund and Epsom College—in regard to difficulties arising over testamentary benefactions. When the exact distinction of bequests by will has been made doubtful between these two bodies by the wording

of the testator's wishes, legal trouble has arisen and much expense has been incurred for legal costs, all of which was a dead loss to one or other or both parties. On the suggestion of the Medical Insurance Agency a joint committee has now been formed comprising three representatives of each party, and it may be confidently hoped that the deliberations of this committee will lead to satisfactory arrangements. The chairman reported to the committee with great regret the death of one of their members, Major Betham Robinson, and the acting secretary of the agency was asked to express to Major Robinson's relatives the sympathy and the real sense of loss felt by the committee.

THE MICHELL CLARKE MEMORIAL FUND.

A STRONG Appeal Committee has been formed with the object of raising a fund to be entitled "The Michell Clarke Memorial Fund," and to be used in behalf of the Medical Library now controlled by the University of Bristol and the Bristol Medico-Chirurgical Society. The late Dr. John Michell Clarke was a distinguished native and citizen of Bristol, who for 30 years worked at the Bristol General Hospital as physician, investigator, and teacher; he was Pro-Vice-Chancellor of the University, as well as joint Professor of Medicine. His energies were largely devoted to the cause of medical education, and the Appeal Committee feel that his memory can be best perpetuated by identifying the Fund with that cause. One phase of higher medical education—to which, moreover, Michell Clarke attributed great importance—is the provision of the best medical literature for the use of practitioners and students. But the Bristol Medical Library, though serving the locality to the top of its powers, rests upon no specific endowment, and the provision of such, it is believed, would fulfil Michell Clarke's wishes. A sum of £2500 will be necessary. Mr. James Rafter, M.A., Registrar of the University, is acting as honorary treasurer, and subscriptions should be forwarded to him at the University, cheques being made payable to the "Michell Clark Memorial Fund."

THE ETIOLOGY OF OVERLAYING.

Dr. F. J. Waldo, coroner for the City of London and borough of Southwark, in his annual report to the corporation of the City, calls attention to the inquests held by him upon the bodies of children suffocated while in bed with their parents or others. These inquests were seven in number, verdicts of accidental death being returned in all cases and the fact of death being due to suffocation proved by post-mortem examination. Dr. Waldo makes a practice of ordering such examinations upon all occasions when suffocation has apparently taken place owing to the child not having been provided with a cot, and it is perfectly clear that he is right. Without post-mortem examination there can be no certainty that the child did not die from natural causes; while, in instances where there is evidence that the adult occupant or occupants of the bed were intoxicated when the death took place, an undeserved charge of manslaughter might follow. It is an opinion held by Dr. Waldo that the intoxication of parents is seldom the cause of infants being overlaid, and naturally it is a matter as to which proof is not always forthcoming. In this connexion, however, it may be pointed out that a post-mortem examination not having taken place when parents have been committed for trial for manslaughter, might lead to the acquittal of guilty persons, as counsel for the defence at their trial would hardly fail to notice the omission of an inquest and to take full advantage of it. It is satisfactory to note that the increased use of cots for their children at night by the humbler classes has led to a very appreciable diminution in the inquests held upon deaths ascribed to suffocation in bed. The number of inquests of this class in England and Wales declined from 1660 in 1904 and 1098 in 1914 to 585 in 1917.

A RETURN TO WHITE BREAD.

THERE is evidence, at all events from some quarters, that the bread supplied now is getting increasingly white in appearance. If that is so, the decisions of the Cabinet announced by the Food Controller in the House of Commons a week ago as to allowing a reduction in the percentage of flour to be abstracted from wheat are being acted upon. Mr. Clynes explained that this step had been taken as a result of the relief of the tonnage situation and because it would release approximately 18,000 tons of offal weekly for farmers, pig-keepers, and others to feed their animal stock, and a certain amount of barley. An economic necessity appears, therefore, to have led the Food Controller to revert to the old order of things in regard to the making of bread from wheat flour, which was alluded to by the Government's own scientific authorities, who, in an official statement issued to the public, said:—

> "We have become accustomed to eat bread made from the inner two-thirds of the wheat grain, the outer third having been given to animals. But at the present time it is important to use as much as possible of the grain for human food, so that wheat flour is ground to contain four-fifths or more of the whole grain. This is an advantage, not only because we get more food, but because the part of the grain which was formerly rejected contains valuable flesh-forming material and salts."

There is a contradiction here in theory or in action which will need further explanation.

FIRST-AID IN ORDINARY LIFE.

DURING the summer we reported briefly in these columns a series of lectures, delivered at the College of Ambulance by representative medical men, the purpose of which was to show the advantage to the community of first-aid on the farm, in the factory, and, generally, in mitigating the results of accidents to life and limb in daily life. In factories and workshops such provision is obligatory under the terms of Home Office regulations, but apart from organised industry, how few are the facilities provided for emergency treatment before the doctor's arrival, even though delay in their application may well make the difference between life and death. We heartily endorse, therefore, the plea of the St. John Ambulance Association that every encouragement should be given to those who desire to gain a competent knowledge of first-aid, home nursing, and hygiene, the Association expressing its willingness to hold classes wherever there is a demand for them. We should like, too, to emphasise the fact that with the cessation of hostilities the knowledge of first-aid and elementary nursing acquired by V.A.D.'s and thousands of others should not be cast off as a garment, but rather put to the gentler uses of peace.

MEMORANDUM ON FOOD AND SCURVY.

BY THE FOOD (WAR) COMMITTEE OF THE ROYAL SOCIETY.

IN view of the fact that outbreaks of scurvy have occurred at various times, both in this country, and abroad in His Majesty's Forces, and in order to guard against a recurrence of such outbreaks, especially at places far removed from sources of supply, the Royal Society Food (War) Committee have issued the following Memorandum, based chiefly upon investigations carried out at the Lister Institute:—

THE CAUSE AND PREVENTION OF SCURVY.

1. Scurvy, like beri-beri, is a "deficiency disease," and is due to the long-continued consumption of food lacking in an accessory food substance or vitamine. The view that scurvy is due to tainted food must be abandoned.

2. This vitamine is contained in a number of fresh foods: in largest amount in oranges, lemons, and fresh green vegetables; in considerable amount in roots and tubers, such as swedes, potatoes, &c.; and in small quantities in fresh meat and milk. It is deficient in all dried and preserved foods.

3. It is destroyed by prolonged heating, such as takes place during stewing. Thus, potatoes in stews would be devoid of vitamine, but if boiled rapidly will still contain some quantity. Alkalies rapidly destroy antiscorbutic properties. Soda should therefore not be added to the water in which vegetables are soaked or boiled.

4. Before the onset of definite symptoms of scurvy there is a period of debility and weakened resistance to disease. The occurrence of cases of debility in any body of troops without sufficient cause should at once direct the medical officer's attention to the sufficiency of the diet.

Prevention of Scurvy.

5. West Indian lime juice, as ordinarily prepared, is useless for the prevention of scurvy. Fresh limes have an antiscorbutic action, but their efficiency is only one-fourth that of lemons. The so-called "lime juice," by the regular administration of which scurvy was eliminated from the Navy during the first half of the nineteenth century, was really lemon juice obtained from the Mediterranean. The history of Arctic exploration affords numerous examples in which scurvy was prevented for long periods of time by the agency of lemon juice regularly taken. Nares's expedition of 1875, notorious for the serious outbreaks of scurvy encountered, was the first to be provisioned with "lime juice" prepared from West Indian limes. Orange juice is as effective as lemon juice.

6. Potatoes and root vegetables have a distinct value in the prevention of scurvy, much less, however, than green vegetables or fresh fruit juices. A daily ration of 14 oz. of potatoes, boiled rapidly but not stewed, will suffice to prevent scurvy.

7. Pulses, beans, peas, and lentils in the dried condition have no antiscorbutic properties. If, however, the dried seeds are soaked in water and are allowed to germinate for a short period, one or two days, they develop the antiscorbutic vitamine. At the same time these pulses are also rich in the vitamine which prevents beri-beri, and are, moreover, valuable foods.

The method adopted for germination is as follows. The beans, peas, or lentils are soaked in water at room temperature (60° F.) for 24 hours. The water is then drained away and, to permit germination, the soaked seeds are spread out in layers, not exceeding 2 to 3 inches in depth, and kept moist for a period of about 48 hours at ordinary room temperature (60° F.). They should not be allowed to dry after this operation, but should be cooked as rapidly as possible (lentils, 20 minutes; peas, 40 to 60 minutes).

8. The antiscorbutic value of fresh meat is very low in comparison with that of fresh vegetables and fruit. If fresh meat is consumed in large quantities, 2 to 4 lb. a day, scurvy will be prevented. Tinned and preserved meat possess no antiscorbutic value. Frozen meat, while more valuable than preserved meat, must be considered inferior to freshly killed meat in this respect.

Methods of Cooking.

9. The destruction of the antiscorbutic properties depends rather upon the time than the temperature employed. All foods, especially vegetable, should be cooked for as short a time as possible at boiling-point. Slow methods of cooking, such as stewing with meat or simmering below boiling-point, should be avoided. Potatoes should be plunged into boiling water and the boiling continued for 20 to 30 minutes after the boiling-point has again been reached. Frozen meat should be roasted when practicable.

The Memorandum closes with a summary of measures recommended for the prevention of scurvy when fresh vegetables are unobtainable: (*a*) The lime-juice ration should be replaced by lemon juice; the ration should be 1 oz. daily served with sugar. (*b*) Cooked germinated peas, beans, or lentils should form part of the regular daily ration. (*c*) Attention should be paid to the methods of cooking employed, as set forth under 9.

THE PARLIAMENTARY REPRESENTATION OF THE SCOTTISH UNIVERSITIES.—Professor William R. Smith requests us to intimate that he will address the graduates of the Scottish Universities at the Royal Institute of Public Health, London, to-day (Saturday) at 4 P.M.

Correspondence.

"Audi alteram partem."

DISPENSARY SUPERVISION IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I can cordially endorse everything written in the article under this heading by Dr. G. Jessel published in your columns on Oct. 26th. This may possibly be the more valuable as the experience which endorses it is obtained in the county borough of Middlesbrough with a population of 126,000 in an area of 6¾ square miles against Wigan's 40 square miles. The same method of home treatment with dispensary attendance and constant nursing supervision has been in operation here for the last four years, and the nursing element is continually growing and still insufficient, although we have three dispensary nurses employed. Recently we have instituted monthly nursing reports on all insured cases, however well they are, with most valuable results. This has been specially demonstrated in controlling the tendency to deteriorating health in the two influenza epidemics. We have also recently added three weeks' holiday in a suitable locality, when needed, paid for by after-care scheme, which is really an essential in those stabilised, if home treatment is to be efficiently carried out. The result of this experiment was very interesting; at first it seemed rather a failure, but a review of the cases two months after demonstrated its unexpected value. The disappointment was due to the fact that only 50 per cent. of the cases sent away were immediately benefited; the unexpected and gratifying result was that in the two months' revision subsequent to their return 75 per cent. were benefited, and this in spite of the fact that we went through the first "flu" epidemic during the holiday period. As this result is rather opposed to sanatorium results the suggestions are very interesting.

There is one other matter suggested by Dr. Jessel's article. During the reconstruction period after the war, with its large housebuilding schemes, it would be worth while considering whether it would not be advisable, when so many of the houses in which the tuberculous live are so unsuitable for their residence, for the local authorities who are rebuilding to reserve certain houses in each area, to be let at a lower rental if necessary to those tuberculous families in need of other quarters, as one of the most economic expenditures in the control of tuberculosis. It is not suggested that these houses should be segregated, unless the local bodies were prepared to spend an extra sum on the beautifying of the area to overcome the natural tendency there would be to consider it a leper area, and so defeat its own ends. May I say that home treatment, to be properly carried out, needs a home, not a hovel, and tuberculosis does not require this more than other diseases.

For home treatment to be successful there must be constant supervision according to the requirements of the case, reasonable freedom from anxiety, and a possibility of removal to a sanatorium, when the extra rest there obtained is an essential consideration. In Middlesbrough the results are fully justifying the idea that the only real way in which tuberculosis can be controlled is by making home treatment and supervision the foundation-stone of the whole structure. Sanatoria, hospitals, and farm colonies should be only separate rooms in the structure for special use; home treatment and supervision must be the foundation of the whole.

I am, Sir, yours faithfully,

H. A. ELLIS,
Tuberculosis Medical Officer.

Middlesbrough, Nov. 16th, 1918.

PS.—Since writing the above I have read Dr. F. E. Wynne's letter in your issue of Nov. 16th. Surely he hardly makes out a case. While admitting the failure in present methods of dealing with tuberculosis, as "vital statistics show no decline whatever, either in the incidence of tuberculosis or the mortality from this cause," he depreciates a method which has at least demonstrated that it has attained the supervision of 1615 cases where before only 1164 were supervised, or that a third of the cases were previously not supervised. At least home supervision does away with many present extravagant and irksome methods, which apparently, in Dr. Wynne's belief, are entirely useless. Whether home supervision and treatment

is the right path remains to be proved, and will in the very nature of things require about ten years to show results. My own, in spite of war food difficulties and influenza, show this year so far a reduction of 20 per cent. on the mortality of 1914, and the more serious cases are undoubtedly diminishing in the district. It is bad policy for those who have so far admitted failure to condemn a method before a reasonable test has been made. War should surely have taught us not to condemn new methods before trial where present procedures are not equal to the undertaking. I trust Dr. Jessel will continue and give us the results of his increased home supervision.

To the Editor of THE LANCET.

SIR,—Your issue of Nov. 16th contained an interesting letter from Dr. F. E. Wynne, medical officer of health of Wigan, on the subject of dispensary supervision in pulmonary tuberculosis. Dr. Wynne maintains that consumptives in Lancashire will not, or do not, carry out such common-sense hygienic methods as they have been taught to do. I have, of course, no knowledge of the county borough of Wigan, but as regards the administrative county as a whole I am convinced Dr. Wynne underrates the average intelligence of Lancashire men and women.

It is a mistake to take dispensary supervision or any other single item in a comprehensive scheme and expect the death-rate from tuberculosis to be much raised or lowered as a consequence of its adoption. In Lancashire, in 1917, no less than 256 persons died from pulmonary tuberculosis who had not been notified, 19 died before receipt of notification, and 433 within three months of notification. Such a reservoir of infection, coupled with other war conditions, makes a much smaller death-rate compared with pre-war years most unlikely, but surely every effort to enable persons suffering from open consumption to have a separate bedroom, as carried out so admirably by Dr. Jessel and the other county tuberculosis officers in the county areas under their charge, helps in the right direction and not in the wrong —I am, Sir, yours faithfully,

G. LISSANT COX,
Central Tuberculosis Officer, Lancashire County Council;
Medical Adviser, Lancashire Insurance Committee.
County Offices, Preston, Nov. 25th, 1918.

TREATMENT OF INFLUENZA.

To the Editor of THE LANCET.

SIR,—Sir Thomas Horder's stimulating article upon the treatment of influenza in your issue of Nov. 23rd will, no doubt, have been read with interest by many of those who are engaged in dealing with the epidemic from the purely clinical side. He rightly points out that there are no reliable short cuts in the treatment of these cases, and emphasises the great importance of skilled nursing and efficient treatment on general lines, especially in the management of the more serious type of case. He speaks of the importance of "the promptness with which the general conduct of the case is established and the thoroughness with which it is carried out," and goes on to add that "every case of the disease treated upon sound principles is a contribution to preventive medicine." The value of such observations cannot be overestimated. Sir Thomas Horder's paper, however, would have been still more helpful if he could have formulated for us a workable scheme for the handling of the many serious cases amongst the poorer classes of the community. His remarks and suggestions about aerotherapy, hydrotherapy, poultices, cradling, inhalations, Gamgee jackets, hypodermic and intravenous medication, to say nothing of the turtle soup, show that he is thinking rather of the patient who is already surrounded by conditions which in themselves tend towards a favourable issue. What, however, are we to do with the serious cases occurring amidst surroundings which from the start are all against recovery? And I take it that these cases are in the majority. Many doctors have by this time realised the hopelessness of treating cases of influenzal pneumonia under such conditions. An abundance of fresh air has been almost unobtainable; efficient nursing in 19 cases out of 20 out of the question, and for those cases—and there have been many of them—situated in houses where the majority of the domestic circle have been laid aside even the elementary requirements of sick nursing have been absent. The harassed doctor has been able to do little more than pay a hurried daily call, prescribe medicine, feel the pulse, and with a word of encouragement pass on to his next patient. Although district nurses have been here and there available—and they have done splendid work under trying conditions—yet for many cases an occasional visit from a kindly neighbour has been all that has been possible. The civilian population has suffered severely, not so much because we have been unable to make up our minds as to the actual causative agent of the disease, or whether one should administer a dose of 10 million or 500 million dead influenza bacilli, or even because we have been unable to provide a definitely curative agent against the virus, but rather owing to the distress and misery caused by the apparent helplessness of the public health, Poor-law, and hospital authorities to do anything adequate to deal with a situation where nursing and care of acutely ill people have been an urgent need.

The difficulties, of course, have been great, but failure to cope with the problem has obviously been due to want of organisation rather than of beds, doctors, and nurses. The war has clearly demonstrated that in the hands of a central authority organisation can overcome everything, and the medical and nursing professions have been able to successfully meet situations of unparalleled difficulty. In one way, therefore, the epidemic has done good. It has proved the urgent need for an efficient State Medical Authority. The existence of such an authority would have made it possible for a clear-cut line of campaign to have been immediately instituted. It would have been possible for that authority to have at once ordered the closing of every hospital and infirmary bed to all but urgent cases. In this way wards could have been set apart and nurses set free for the care of large numbers of influenzal pneumonias. Under such conditions it would have been reasonably possible to attempt to carry out Sir Thomas Horder's most excellent principles of treatment and so give the patients a better chance, and at the same time to have saved many families from the distress and misery produced by attempting to look after acutely ill relatives under conditions that are all against recovery.

I am, Sir, yours faithfully,

Leeds, Nov. 25th, 1918. C. W. VINING, M.D.

PARLIAMENTARY REPRESENTATION OF DUBLIN UNIVERSITY.

To the Editor of THE LANCET.

SIR,—I wish to remind medical graduates of Dublin University that by recent legislation all graduates who register their names have the right to vote; the franchise is not, as heretofore, confined to holders of the higher degrees. In order to register, a graduate not already registered should send without delay to the Assistant Registrar of University Electors, Trinity College, Dublin: (1) his name in full; (2) his address; (3) the registration fee of £1; (4) a declaration that he, or she, is of the required age and a British subject. Women graduates have the same rights as men.

Sir Robert Woods, who received wide support at the last election, has announced his intention of contesting the vacant seat. If Dublin University is to return a medical man as one of its Members it is incumbent on medical graduates to register as voters at once. It is not necessary to impress on readers of THE LANCET the importance of returning an increased number of competent medical men to Parliament.

I am, Sir, yours faithfully,

Dublin, Nov. 25th, 1918. ROBERT J. ROWLETTE.

THE INTRAMUSCULAR ADMINISTRATION OF NOVARSENOBILLON.

To the Editor of THE LANCET.

SIR,—As the method which I have adopted of administering novarsenobillon intramuscularly appears to be practically painless, and as other practitioners may be interested, may I be allowed to state the technique employed? The successful and comparatively painless administration of novarsenobillon depends in the first place upon a satisfactory solvent being used for the drug. Many solvents and methods were tried at St. Thomas's Hospital, with the result that a solution of guaiacol in liquid glucose proved to be the most satisfactory. The solution is thus prepared:—

Guaiacol	1 part.
Liquid glucose	50 parts.
Water (recently sterilised)	to 100 parts.

The water and glucose are sterilised and the guaiacol is added when cold.

It is to be noted that the solution is prepared without the addition of any anæsthetising agent, such as stovaine or novocaine. Experiments made with higher percentages of both guaiacol and liquid glucose were found to be unsatisfactory.

There are many qualities of liquid glucose, varying in colour from dark brown to yellow, but the product used should be the pure substance, which is clear and colourless. Of this solvent, 10 to 20 minims are taken and the novarsenobillon powder is dissolved in it, which it readily does, even when the dose is as large as 0·75 g. With this amount of liquid the injection is made. This amount is very small, which is of great importance, as the least bulk of fluid possible should be injected into the tissues.

I do not consider the addition of a local anæsthetising agent necessary, for with intramuscular injections pain makes no appearance until several hours after giving the drug, and by that time the effect of a local anæsthetic has disappeared. If the injection is skilfully administered there is no pain at the time of administration and the insertion of the needle is not felt.

The method recommended is to take a 1 c.cm. tuberculin or intramuscular syringe fitted with a fine intramuscular needle. Separating the needle from the syringe and holding it between the thumb and forefinger, it is stabbed with a rapid movement of the wrist into the glutei in the upper and outer quadrant of the buttock, causing it to enter the tissues at right angles to the skin. The depth to which the needle is inserted—usually from three-quarters up to the hilt—can only be gauged by practice. The buttock should be carefully palpated beforehand to ascertain the best position for inserting the needle and the force requisite to drive the needle to the desired depth. When this has been done the syringe is fitted on to the needle, care being taken that the needle is kept stationary while it is in the tissues and while the plunger is being pushed down. The needle and syringe are then withdrawn as one, as rapidly as possible to prevent any solution remaining along the track of the needle. The buttock is then gently massaged for five minutes.

Although a few patients have complained of pain lasting for two or four hours this is exceptional. By this method I find that patients are spared the intense pain which often attends the administration of the drug with the solvents generally in use.

I am, Sir, yours faithfully,

THOS. ANWYL-DAVIES,

In charge of the Venereal Department, St. Thomas's Hospital.

13, Park-place, St. James's, S.W., Nov. 23rd, 1918.

SECURITY OF TENURE FOR MEDICAL OFFICERS OF HEALTH AND INSPECTORS OF NUISANCES.

To the Editor of THE LANCET.

SIR,—As the time is approaching when, I think, an application might be made to the Local Government Board for the issue of the Order referred to in the enclosed letters, I send you copies of the letters for publication.

I am, Sir, yours faithfully,

Nov. 23rd, 1918. PHILIP MAGNUS.

[ENCLOSURES.]

Local Government Board, Whitehall, S.W. 1,
30th December, 1915.

MY DEAR MAGNUS,—In accordance with the decision of my predecessor, which was contained in his letter to you of February last, my Department have prepared an Order giving security of tenure to whole-time medical officers of health and inspectors of nuisances in the future.

I entirely agree with the decision at which Mr. Samuel arrived, and am strongly in favour of security of tenure for these officers, but I must confess that my own feeling is that the present is hardly the most appropriate time for the issue of such an Order, in view of the fact that so many of our best men have given up local work for service with the Army or Navy, and that the conditions are now quite abnormal.

Perhaps you would kindly let me know what your views are and whether in the circumstances you would see any objection to the issue of the Order being further postponed.—Yours sincerely,

(Sgd.) WALTER H. LONG.

Local Government Board, Whitehall, S.W. 1,
7th January, 1916.

MY DEAR MAGNUS,—Many thanks for your letters with respect to the tenure of office of medical officers of health and inspectors of nuisances. I felt sure you would agree that there were good grounds for postponing the intended change.

I see no objection at all to your publishing our correspondence.

Yours sincerely,

(Sgd.) WALTER H. LONG.

I am very grateful to you for your most valuable and friendly coöperation.—W. H. L.

The War and After.

SUMMARY OF TOTAL WAR CASUALTIES.

WE gave last week Mr. Macpherson's statement to the House of Commons regarding the total British casualties, including those of Dominion and Indian troops, up to Nov. 10th. This referred to land warfare. The Secretary of the Admiralty has issued a corresponding statement regarding naval losses. From the outbreak of the war up to Nov. 11th last there was a total of 39,766 casualties in the Royal Navy and Royal Marines, excluding the Royal Naval Division (included in the War Office figures), but including the Royal Naval Air Service up to the end of last March. The figures also include a certain number of officers and men of the Mercantile Marine injured while serving on commissioned vessels. The total naval casualties are analysed as follows:—

Naval Losses.

	Officers.	Men.
Dead (including died from wounds and from other causes)	2,466	30,895
Wounded	805	4,378
Missing	15	32
Interned and prisoners of war	222	953
Total	3,508	36,258

In addition to these, 14,661 officers and men of British merchant ships and fishing vessels have lost their lives through enemy action, and 3295 others have been captured and detained in enemy countries as prisoners of war.

Canadian Losses.

An official statement gives the total casualties to Nov. 5th last in the Canadian Overseas Forces as 213,268:—

Killed in action	35,128	Missing	842
Died of wounds	12,048	Wounded	154,361
Died of disease	3,409	Prisoners of war	2,860
Presumed dead	4,620		213,268

American Losses.

In an interview given at Washington, General Peyton March gave the casualties during the war in the U.S.A. Army:—

Killed or died of wounds	36,154	Wounded	179,625
Died of disease	14,311	Prisoners	2,163
Deaths uncertified	2,204	Missing	1,160

Indian Casualties.

The total number of casualties among the Indian troops up to Sept. 30th last has been officially given as 101,439, viz.:—

	Killed.	Wounded.
In Mesopotamia	14,742	30,589
In France	6,900	16,380

THE CASUALTY LIST.

The following medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. R. Clark, R.A.M.C., attached Hussars.

Died of Wounds.

Lieut.-Col. P. S. O'Reilly, C.M.G., R.A.M.C., qualified in Ireland in 1899, and joined R.A.M.C. shortly afterwards. He took part in the South African War, and at the time of his death was senior medical officer at the Royal Arsenal, Woolwich.

Died.

Capt. M. W. Miles, R.A.M.C., qualified in London in 1917, and thereupon joined up. He died in England of pneumonia following influenza.

Capt. E. D. Keane, R.A.M.C., was a student at Aberdeen University and qualified in 1901. He held appointments at the County Asylum, at Chalmers' Hospital, and at the Dispensary, Banff, and was in practice at Kensington at the time of joining the R.A.M.C.

Major W. S. MacDonell, Canadian A.M.C.

Capt. M. S. K. R. Rao, I.M.S.

Major G. G. Anderson, R.A.M.C.

Surgeon-Lieut. J. F. Howell, R.N.

Surgeon Sub-Lieut. J. D. Gear, R.N.V.R.

Wounded.

Capt. J. J. B. Edmond, R.A.M.C., attached K.R.R.C.

Capt. G. Robinson, R.A.M.C.

Lieut. W. H. Ross, R.A.M.C., attd. Devonshire Regiment.

Capt. A. W. Raymond, M.C., R.A.M.C., attd. Rifle Brigade.

Capt. Santokh Singh, I.M.S.

Capt. W. G. MacKenzie, M.C., R.A.M.C.

Previously Reported Wounded, now Reported not Wounded.

Capt. W. G. Shakespeare, R.A.M.C.

OBITUARY OF THE WAR.

JAMES MURRAY McLAGGAN, M.B., CH.B. ABERD.,

MILITARY CROSS,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain J. M. McLaggan, who was killed in action on Oct. 4th, was elder son of James McLaggan, of Torphins, Aberdeenshire. He was educated at Gordon's College, Aberdeen, and graduated M.B., Ch.B. at the University in July, 1913. He was then appointed house physician at the Royal Infirmary, and was holding this post when, at the outbreak of war, he received a commission in the R.A.M.C. After a period of service at Netley Hospital he was attached to the Royal Fusiliers, serving with his battalion in Egypt, Salonika, and France for three and a half years. At the battle of Loos he was awarded the Military Cross—

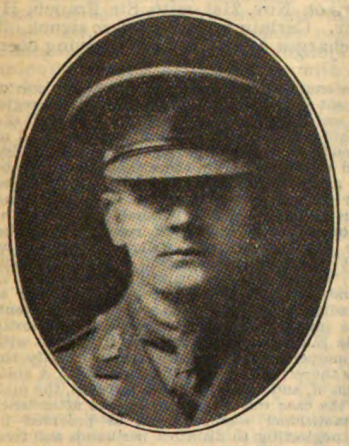
"For conspicuous gallantry and devotion to duty during the operations 27th to 30th September, 1915, when he attended to the wounded in the firing line under heavy shell and rifle fire. His coolness and skill undoubtedly saved many lives. For three days and four nights he worked incessantly with unflagging energy."

He was killed by a machine-gun sniper. The A.D.M.S. of the division writes: "Captain McLaggan had a very high sense of duty, and his constant thought was for the well-being of the men. The manner of his death was exactly like his life—with complete disregard of his personal safety he went to attend to his fallen C.O. when he himself fell a victim."

FRANK OSWALD SPENSLEY, M.R.C.S. ENG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain F. O. Spensley, who died at Weymouth on Oct. 23rd, at the age of 39 years, was youngest son of the late Rev. James Spensley, of Reeth, N. Yorks. Educated at Kingswood School, Bath, and at St. Thomas's Hospital, London, he held a house appointment at Lowestoft Hospital before being appointed in May, 1908, assistant medical officer to the Darenth Asylum. Four years later came his promotion to the senior post. He was keenly interested in the scheme of industrial training for the feeble-minded, and assisted wholeheartedly in making Darenth a success as an industrial colony. His paper read before the Medico-Psychological Association was noticed in our columns (THE LANCET, 1913, i., 711). Volunteering for active service on the outbreak of war, he was at first rejected on medical grounds, but received a commission in the R.A.M.C. in November, 1916, and served for a year with the Salonika Force, when he was invalided home. After working at Aldershot and at Wareham he was attached to the R.A.F. at Blandford, where he was at work until Oct. 22nd. On the following day he died of pneumonia at the Borden Military Hospital, Weymouth. Captain Spensley's constant thought, both at Darenth and at the camp, was for his patients, by whom he was much beloved. His chief at Darenth writes: "He had qualities which eminently fitted him for that branch of work—I mean a large sympathy and a keen interest in the lives of the patients. He was consequently very popular among them."



HUGH BERNARD GERMAN, M.R.C.S. ENG.,

MILITARY CROSS,
MAJOR, ROYAL ARMY MEDICAL CORPS.

Major H. B. German, who was killed in action in France on Sept. 18th, was eldest son of the late George Alexander German, of Southsea. He was educated at Portsmouth Grammar School, where he was distinguished in games, and took his medical course at Guy's Hospital, London, qualifying in 1904. He then entered the Royal Navy and was serving on H.M.S. *Orontes* in the Mediterranean at the time of the Calabrian earthquake, when he was in one of the first relief parties which reached the scene of disaster. For his services on this occasion he received the Messina Medal and the Order of the Crown of Italy. In 1913 he went into private practice at Waltham Abbey, surrendering it in 1916 when offered a temporary commission as captain in the Royal Army Medical Corps. He was sent to France attached to the 17th Field Ambulance, was mentioned in despatches in 1917, and in November of the same year was awarded the Military Cross for gallantry in the field, to which he added a bar in March, 1918. He met his death while going to the succour of a wounded officer. His brother officers write of the esteem and respect in which Major German was held by all ranks. "He was fearless and untiring in his efforts for the wounded."

JAMES HARRIS CONNOLLY, M.D. EDIN., F.R.C.S. ENG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain J. H. Connolly, who died on active service on Oct. 23rd, was second son of James Connolly, of Putney. He was educated at the Royal Academical Institution and at Queen's College, Belfast, going on to Edinburgh University, where he qualified M.B., Ch.B. in 1902 and M.D. with honours four years later. During these years he acquired his surgical experience, which was considerable, at the Devonport and Chesterfield Hospitals. The next 18 months he spent at the Golden Square Throat Hospital, and his interest in special surgery thus aroused he took his F.R.C.S., and was appointed honorary assistant throat and ear surgeon to St. Bartholomew's Hospital, London, and to the Hackney Hospital for Children. He was securing a position as a consultant in this branch when, on the outbreak of war, he offered his services, and was at first placed in charge of wounded officers at the Royal Herbert Hospital, Woolwich. He was in Egypt for some months, but for the greater part of the four years was working at a C.C.S. in France, exposed to great climatic hardships. In March, 1917, he was invalided after a severe chill and later, having collapsed while operating, was found to have albuminuria. After six months at the Acheson Hospital in London he returned to France and died of exhaustion at the C.C.S., where he was surgeon-specialist. Captain Connolly's friends one and all write of his forgetfulness of self and devotion to duty. His work always took the first place with him and he was a very skilful surgeon. "He was too much wrapped up in his work to have a large circle of friends, but to those with whom he was intimate he was geniality itself."

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Capt. H. P. D. Helm, R.A.F., late Border Regiment, died from illness contracted on active service, eldest son of Dr. R. D. Helm, of Carlisle.

Lieut. M. E. J. Moore, M.C., Royal Irish Rifles, died of wounds, only son of Dr. E. E. Moore, of Donegal Asylum, Letterkenny.

Capt. H. T. F. Russell, M.C., R.A.F., late Royal Welsh Fusiliers, killed in an aeroplane accident, third son of Dr. W. F. Russell, of Holyhead.

Lance-Corpl. T. P. Clark, Royal Fusiliers, killed in action, only surviving son of the late Dr. A. W. Clark, of Wisbech, Cambs.

Lieut.-Col. A. Thorp, D.S.O., R.A., killed in action, eldest surviving son of the late Dr. C. W. Thorp, of Todmorden, Lancs.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Licences in Dental Surgery were recently conferred upon 19 candidates (including two women) who have passed the requisite examinations and have complied with the necessary by-laws. The following are the names of the successful candidates:—

Douglas William Smale Adams and John Frederick Batsford, Guy's Hosp.; Isaac Myer Benischowitz, Middlesex and Royal Dental Hosps.; Iris Elizabeth Gardiner, Royal Free and National Dental Hosps.; Myer Garfinkel, Univ. Coll. and National Dental Hosps.; Mabel Francis Humby, Royal Free and Univ. Coll. Hosps.; John James and Elisha Clemens Keet, Guy's Hosp.; Frank Lawrence, Lond. Hosp.; Harold James Lyon and Amin Maher, Guy's Hosp.; Cornelis Hermanus Oliver, Middlesex and Royal Dental Hosps.; Charles Lindley Donald Pasmore, Guy's Hosp.; Clifford Thomas Plimsoll, Charing Cross and Royal Dental Hosps.; Bertram Adolphe Siedle, Univ. Coll. and National Dental Hosps.; and William Wallace Harold Truscott, William Henry Turner, and Richard Murray Underwood, Guy's Hosp.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful:—

THIRD (M.B., B.S.) EXAMINATION FOR MEDICAL DEGREES.

Loveday Shackell Banes, St. Mary's Hosp. and Lond. Sch. of Med. for Women; Irene Bastow, Lond. Sch. of Med. for Women; Stanley Batchelor, Lond. Hosp.; Alethea Josephine Bolton, Birm. Univ.; Philip Crawford Conran, Middlesex Hosp.; Hilda Margaret Denton and Susan Alfreda Finch, Lond. Sch. of Med. for Women; Humphrey Leonard George Foxell, Univ. Coll. Hosp.; Maud Gazdar, Lond. Sch. of Med. for Women; Johan Coenraad Gie, Guy's Hosp.; Lionel Bernard Goldschmidt, King's Coll. Hosp.; Charles Hamilton Gould and Walter Henry Grace, Guy's Hosp.; Blanche Aspasie Marion Henderson, Charing Cross Hosp.; William Broke Heywood-Waddington, St. Bart.'s Hosp.; Robert Hamer Hodges, King's Coll. Hosp.; Edwin Augustus Hutton-Attenborough, London Hosp.; Muriel Elsie Landau, Lond. Sch. of Med. for Women; Janet McAllister McGill, St. Mary's Hosp. and Lond. Sch. of Med. for Women; Maurice William Holt Miles, St. Thomas's Hosp.; Ludlow Murcott Moody, King's Coll. Hosp.; Percival George Quinton and Walter Murad Abdul Rahman, Univ. Coll. Hosp.; Olive Rendel, Lond. Sch. of Med. for Women (honours, distinguished in pathology); Enid Eleanora Sanger-Davies, Lond. Sch. of Med. for Women; Stanley Nahum Sennett, London Hosp.; Joseph Harold Sheldon, King's Coll. Hosp.; Aubrey Leonard Telling, Leeds Univ.; and Gladys Millicent Rutland Webster, Lond. Sch. of Med. for Women.

B.S. EXAMINATION.

Thomas Henry Sanderson-Wells, Middlesex Hosp.

The following candidates have passed in one of the two groups of subjects:—

Group I.—Simon Cyril de Silva Wijeyeratne, Univ. Coll. Hosp.; Alice Muriel Griffiths and Mary Isabella Hounsfield, Lond. Sch. of Med. for Women; Francis Reginald Law, Leeds Univ.; Annie Lloyd, Lond. Sch. of Med. for Women; Thomas Dawson Pratt, Leeds Univ.; and Henry Bret Russell, St. Thomas's Hosp.

Group II.—Charles Yarrow Eccles, St. Thomas's Hosp.; Albert William Holgate, Univ. Coll. Hosp.; Ifor Hughes Lloyd, Westminster Hosp.; Alice Lloyd Lloyd-Williams, St. Mary's Hosp. and Lond. Sch. of Med. for Women; Adeline Mabel Matland and Enid Maud Pfeil, Lond. Sch. of Med. for Women; and Montagu Cecil Polhill, Univ. Coll. Hosp.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—M. Girgis (Sect. II.), Univ. Coll. Hosp.; D. M. Howard (Sects. I. and II.), St. Mary's Hosp.; and T. T. Tiplady (Sect. I.), Durham.

Medicine.—D. M. Howard (Sects. I. and II.), St. Mary's Hosp.; S. Robinson, St. Thomas's Hosp.; S. H. Robinson (Sects. I. and II.), Guy's Hosp.; and G. E. Spero (Sect. I.), London Hosp.

Forensic Medicine.—D. M. Howard, St. Mary's Hosp.; W. A. Jones, Glasgow; S. H. Robinson, Guy's Hosp.; and C. de B. Thomson, Middlesex Hosp.

Midwifery.—R. A. D. J. Bernhardt, Middlesex Hosp.; J. Crawford, Royal Free Hosp.; D. M. Howard, St. Mary's Hosp.; T. T. Tiplady, Durham; and J. Yates, Manchester.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: M. Girgis and D. M. Howard.

ROYAL INSTITUTION OF GREAT BRITAIN, ALBEMARLE-STREET, PICCADILLY, W.—A general monthly meeting of the members will be held on Monday, Dec. 2nd, at 5 P.M.

ROYAL MEDICAL BENEVOLENT FUND.—At a meeting of the committee, held on Nov. 8th, 30 cases were considered and £249 15*s.* voted to 24 of the applicants. The following is a summary of some of the cases relieved:—

L.R.C.P. & S. Irel., aged 34, unmarried, and practised in India, where he contracted fever, and as a ship's surgeon. Suffered from insomnia and had to discontinue work owing to the morphia habit. Now reported cured, and wishes to start a practice. Quite without means. Voted £5.—Widow, aged 47, of L.R.C.P. & S. Edin. who practised at Walthamstow and died in 1916, and was an annuitant of the Fund. Applicant left entirely without means, and finds it difficult to obtain suitable employment. Relieved three times, £18. Voted £12 in 12 instalments.—M.R.C.S. Eng., aged 49, married, and practised at Birmingham. Suffering from disseminated sclerosis. Has no income beyond 10*s.* a week from friends and 5*s.* a week earned by his wife by making shell jewellery. Rent £6 a year. One son, aged 11, a foundation scholar at Epsom. Relieved twice, £44. Voted £26 in 12 instalments.—Widow, aged 43, of L.R.C.P. & S. Edin. who practised in Ireland and died in 1912. Applicant obtained a living by keeping a sweet shop, but owing to the war had to give it up. Now earns 10*s.* a week by sewing. Has three children, ages 13–18. The eldest in the Army, from whom she receives 3*s.* 6*d.* a week, and a daughter aged 16, who earns 12*s.* a week. Recommended by the Edinburgh Branch of the Guild. Relieved twice, £25. Voted £15 in three instalments.—Daughter, aged 66, of L.F.P.S. Glasg. who practised at Widnes and died in 1863. Applicant has two pensions bringing in £40 a year and has two unfurnished rooms rent free. Owing to the high cost of living unable to manage. Relieved five times, £25. Voted £5.—Widow, aged 55, of M.B. Aberd. who practised at Watlington and died in 1912. Owing to ill-health unable to work. Sister-in-law allows 10*s.* a week. Rent 5*s.* a week. Relieved three times, £34. Voted £12 in 12 instalments.—Widow, aged 37, of L.R.C.P. Edin. who practised at Edinburgh and died in 1916. Applicant was left with very limited means with four children, now aged 4–12 years. Tries to supplement her income by taking in boarders. Relieved twice, £27. Voted £15 in 12 instalments.—Daughters, aged 56 and 44, of L.S.A. Lond. who practised in London and died in 1903. Both are chronic invalids and unable to work, and their joint income is less than £70 a year. Relieved ten times, £119. Voted £18 in 12 instalments.—Widow, aged 81, of M.D. Lond. who practised in London and died in 1895. Suffers from chronic rheumatism. Total income £44 a year. Relieved ten times, £65. Voted £10 in two instalments.—Widow, aged 73, of L.R.C.P. Edin. who practised in East London and died in 1913. Owing to long illness of husband was left quite unprovided for. Has three daughters, but none able to help. Brother who used to help her now dead. Only income a pension from a City Company. Relieved five times, £60. Voted £12 in 12 instalments.—Widow, aged 55, of M.D. Edin. who practised at Newcastle and died in 1896. Was left with one daughter entirely unprovided for. Has recently fractured her leg, which has prevented her from working. Receives a little help from daughter. Relieved four times, £48. Voted £12 in 12 instalments.—Daughters, aged 67 and 58, of M.R.C.S. Eng. who practised in Cornwall and died in 1873. Endeavour to make a living by taking in paying guests, but cannot make sufficient to pay expenses. Relieved nine times, £154. Voted £18 in 12 instalments.

Subscriptions may be sent to the acting honorary treasurer, Dr. Samuel West, at 11, Chandos-street, Cavendish-square, London, W. 1.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Queen Anne's Gate-buildings, Westminster, on Nov. 21st, with Sir Francis H. Champneys in the chair. Certain midwives were struck off the Roll, the following charges, amongst others, having been brought forward:—

Being in attendance at a confinement, and the case being one of abortion, the midwife did not explain that the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (2), and the case being as aforesaid she neglected to band to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to a medical practitioner or to an approved institution, as required by Rule E. 21.—A midwife when attending her patients did not wear a clean dress of washable material, as required by Rule E. 2; she did not take and record the pulse and temperature of her patients at each visit, as required by Rule E. 14; she did not enter her records of pulse and temperature in a note-book or on a chart carefully preserved, as required by Rule E. 14, and did not keep her register of cases as required by Rule E. 24. Medical aid having been sought for a patient, the midwife neglected to notify the local supervising authority thereof, as required by Rule E. 22 (1) (*a*); having been in contact with a patient suffering from puerperal fever, she neglected to notify the local supervising authority thereof, as required by Rule E. 6. A child suffering from inflammation of, and discharge from, the eyes, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (5). A midwife neglecting to disinfect her hands and forearms on each occasion before touching the generative organs of the patient, as required by Rule E. 4.; neglecting to wash the patient's external parts with soap and water and then to swab them with an efficient antiseptic solution on the occasions required by Rule E. 8, and attempting to assist delivery of the placenta by traction on the cord, being thereby guilty of malpractice within the meaning of Section 8 (2) of the Midwives Act, 1902. A midwife being

drunk and incapable of giving proper attention to the patient; neglecting to examine the placenta and membranes and to satisfy herself that they had been completely removed, as required by Rule E. 10. That medical advice on account of serious skin eruptions having been sought for the infant children of three women upon whom she was in attendance as a midwife, the midwife neglected to notify the local supervising authority thereof, as required by Rule E. 22 (1) (a). That when called to a confinement the midwife did not take with her the appliances and antiseptics required by Rule E. 3. In disregard of Rule E. 12 the midwife discontinued her attendance at a time when the condition of the child was not normal.

At a meeting held on the same day a letter was read from the Local Government Board asking the Central Midwives Board to consider the advisability of framing a new rule in terms similar to the corresponding rule of the Central Midwives Board for Scotland, which required a midwife to notify the local supervising authority in the following case: "Artificial feeding: Whenever under Rule 19 (b) she has advised the substitution of artificial feeding for breast feeding." The Board decided that the Local Government Board be informed that the Central Midwives Board, having considered the question of framing a new rule in terms similar to the corresponding rule of the Central Midwives Board for Scotland, is prepared to submit such a rule for the approval of the Privy Council.—A letter was considered from the secretary of the Four Boroughs Maternity Clinics bringing to the notice of the Board a scheme for the payment of midwives for antenatal visiting. The Board directed that the secretary of the Four Boroughs Maternity Clinics be thanked for her communication, of which the Board takes note. The Board fears that any scheme by which additional payment is made to midwives for bringing patients to a clinic can hardly fail to be utilised for the notification of pregnancy, and therefore to prevent early engagement of midwives. It is strongly in favour, however, of promoting the coöperation of midwives in antenatal and maternity care.—A letter was considered from the secretary of the National Poor-Law Officers' Association asking the Board to amend Rule C. 1 (2) (b) by deleting the words "and maintaining a resident physician or house surgeon and a matron or superintendent nurse." The Board decided that the secretary of the National Poor-Law Officers' Association be informed that the Board is not prepared to amend Rule C. 1 (2) (b) in the sense suggested by his letter.

THE INSURANCE OF DISABLED MEN.—The Government has decided to apply the Workmen's Compensation Act to disabled sailors, soldiers, and airmen returning to civilian employment, it being understood that the State bears any increased charge incurred for compensation which arises out of the disability. The ordinary rates of insurance are to rule, the Government reimbursing the loss, if any, to the insurance company or to the large firm which undertakes the insurance of its own workpeople. All men in receipt of disability pensions from the Ministry of Pensions are regarded as disabled men for the purposes of the scheme. The details of the scheme are still to be published.

DEARTH OF WOMEN DOCTORS.—A scarcity of women medical assistants for maternity and child-welfare schemes is recorded by the Leeds Health Committee. There were only two applications in response to an advertisement for a woman medical assistant. Only one of the applicants was deemed suitable, but she failed to attend for an interview. The medical officer reported that Dr. Amelia Sharp had intimated her willingness to undertake a certain amount of work in connexion with infant-welfare centres, and the committee has agreed to ask her to attend at three afternoon clinics a week and to pay her at the rate of 1 guinea per clinic. The medical officer has been empowered to make such arrangements with other medical practitioners of carrying on the work at the centres temporarily at a similar rate of remuneration.

CLERICAL, MEDICAL, AND GENERAL LIFE ASSURANCE SOCIETY.—The report of this society presented at the ninety-fourth annual general meeting, which was held at the Society's office, 15, St. James's-square, S.W. 1, on Nov. 1st, showed a satisfactory development of the business and of financial progress during the year ending June 30th. The new assurances were 808, for a total sum of £1,122,937. The premium income was £476,311, showing an increase of £7966, and the gross interest income rose by £7072 to £292,412. The claims by death, including £43,199 directly due to war, amounted to £323,633, which is £36,851 below the total recorded last year. The surplus income of the year's transactions amounted to £217,150, and the life assurance fund was thereby raised to £6,312,720. The society has resumed its pre-war practice of granting whole-world and unconditional policies on the lives of civilians at the ordinary rate, and it also grants whole-world and unconditional policies at extra premiums on the lives of naval and military officers serving at home and abroad.

THE SERVICES.

ROYAL AIR FORCE.

A LIST of some 200 officers of different ranks in the Naval and Army Medical Services who have received temporary commissions in the Royal Air Force (Medical Branch) will appear in a subsequent issue of THE LANCET.

ROYAL NAVAL MEDICAL SERVICE.

To be temporary Surgeon-Lieutenants: J. Nicol, A. W. McRorie.

ARMY MEDICAL SERVICE.

Col. J. Meek, C.B., is placed on retired pay.

ROYAL ARMY MEDICAL CORPS.

To be temporary Colonels whilst specially employed: Major G. R. Murray, R.A.M.C., T.F.; Temp. Lieut.-Col. E. F. Buzzard (Captain, R.A.M.C., T.F.).

Major R. N. Hunt relinquishes the temporary rank of Lieutenant-Colonel on re-posting.

Temp. Lieut.-Col. T. D. Acland (Major and Brevet Lieutenant-Colonel, R.A.M.C., T.F.) relinquishes his temporary commission on re-posting.

Capt. A. D. Fraser relinquishes the acting rank of Lieutenant-Colonel and reverts to the acting rank of Major.

Major W. Davis to be acting Lieutenant-Colonel whilst in command of a Medical Unit.

Temp. Capt. W. F. Neil and Capt. C. J. O'Reilly relinquish the acting rank of Major on re-posting.

To be acting Majors: Capts. J. Y. Moore, W. F. Christie; Temp. Capts. S. J. L. Lindeman, W. G. Waugh, S. W. McLellan, A. J. M. Wright, R. E. Cree, N. S. Carmichael.

Capt. (acting Major) A. G. Wells to draw the pay and allowances of his acting rank whilst specially employed.

Temporary Captains to be acting Majors whilst specially employed: C. S. Gideon, R. W. Sutherland, L. J. Spence.

The undermentioned late temporary Captains are granted the honorary rank of Captain: M. M. Townsend, T. E. Hammond, G. Holroyd.

Temp. Hon. Lieut. J. R. Beaven to be temporary honorary Captain.

Officers relinquishing their commissions: Temp. Major B. G. Elliott (on account of ill-health contracted on active service, and is granted the honorary rank of Major); Temp. Capts. (acting Major) W. P. Ker, N. C. Rogers, C. F. Curtis, H. Dearden (on account of ill-health caused by wounds, and is granted the honorary rank of Captain), W. Russell, D. G. M. Munro, J. W. O. van Millingen (on account of ill-health contracted on active service, and is granted the honorary rank of Captain), W. H. Bennett (on account of ill-health contracted on active service, and is granted the honorary rank of Captain), J. St. P. Knight, L. C. Smith (on appointment to R.A.F.), W. Allan (on account of ill-health contracted on active service, and is granted the honorary rank of Captain), T. B. Carlyon (on account of ill-health, and is granted the honorary rank of Captain).

SPECIAL RESERVE OF OFFICERS.

Capt. T. F. Corkill to be acting Major.

Capt. J. A. L. Wilson to be acting Major whilst specially employed.

Capt. J. MacD. Clark relinquishes his commission on account of ill-health contracted on active service, and is granted the honorary rank of Captain.

To be Lieutenants:—L. Hardy. From University of London Contingent, O.T.C.: E. A. Clegg, A. Eidinow, S. V. Goldhurst, G. G. Havers, W. S. Herman, C. P. Hines, C. G. J. Rayner, M. S. Thomson, J. Whittingdale. From Birmingham University Contingent, O.T.C.: E. E. R. Spurway.

TERRITORIAL FORCE.

Lieutenant-Colonels, from the Sanitary Service, to be Lieutenant-Colonels: P. C. Smith, J. R. Kaye, A. K. Chalmers, D. Smart, and C. Averill.

The undermentioned Majors to be acting Lieutenant-Colonels whilst specially employed: W. H. M. Telling, W. Thompson, W. M. Stevens, P. R. Griffiths, B. Riddell, G. N. Biggs (to remain seconded), D. J. Graham, H. A. Ballance, H. B. Roderick, and L. Humphry.

Capt. (Brevet Major) E. H. Fenwick to be acting Lieutenant-Colonel whilst specially employed.

Captains to be acting Majors while specially employed: R. C. Elsworth, W. J. Greer, T. M. Thomas, E. Reid, J. Henderson, H. J Gorrie, F. S. Carson, (Brevet Major) A. G. R. Foulerton, (Temp. Major) A. A. McWhan, J. H. Cobb, A. J. Jex-Blake, J. H. Thursfield, J. R. Levack, R. Ritson, J. Everidge, M. G. Foster, H. A. Cookson, R. Whittington, W. H. Brailey, A. L. Whitehead, L. R. Braithwaite, R. A. Veale, C. W. Vining, A. H. Horsfall (to remain seconded).

Lieut. C. H. Gibb to be Captain.

Restored to the establishment: Major (Brevet Lieut.-Col.) T. D. Acland; Capts. N. S. Finzi, A. McLennan.

TERRITORIAL FORCE RESERVE.

Capt. H. G. Butterfield relinquishes his commission on account of ill-health, and is granted the honorary rank of Captain.

Capt. A. L. McCully, from Attached to Units other than Medical Units, to be Captain.

INDIAN MEDICAL SERVICE.

Cols. C. C. Manifold and P. Hehir to be Major-Generals.

Hon. Temp. Lieut. Behramji Pestonji Sabawala to be honorary temporary Captain.

THE British Red Cross Society have conferred the honour of honorary life membership upon Mr. John Hatton, director of the baths of Bath, in recognition of the work done at the bathing establishment for wounded and invalided soldiers of all ranks. Immediately after the outbreak of war the Bath Corporation placed the facilities of the city's bathing establishment at the disposal of the War Office and Admiralty.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

—o—

TUESDAY, NOV. 26TH.

THE General Medical Council commenced its winter session at its offices, Hallam-street, W., Sir DONALD MACALISTER, the President, being in the chair.

Presidential Address.

Sir DONALD MACALISTER opened his address with an expression of thanksgiving for the assured peace, and of grateful acknowledgment to those who by their devotion and sacrifice had redeemed civilisation from ruin. He continued:—

Not least we recognise with pride the great part performed by the men and women of our profession, both at home and abroad, in preserving the health of the Forces and of the people during the struggle. In the King's words, they have made a "notable contribution to the common welfare," "fearlessly exposing themselves to danger in their task of mercy." The profession as a whole is the nobler for their nobility, and will face the grave tasks of reconstruction with fresh courage, informed by their example and experience.

Sir Donald MacAlister went on to mourn the loss to the Council in the death of Mr. Meredith Townsend, who joined the Council last year, and of his former colleagues, Mr. Brudenell Carter and Dr. Robert Saundby, each of whom had given many years of valued service before retirement. He reported the death, in advanced age, of Mr. James Robertson, Registrar of the Branch Council for Scotland. He regretted the absence of two members of the Council—Sir Frederick Taylor and Professor Symington—owing to ill-health.

The Effects of the War and Reconstruction.

The effects of the war, which were still felt by the medical profession, were then referred to.

The strain upon medical men in civil practice, already severe enough, has been increased by the prevalence of epidemic illness. There is good hope, he said, that this strain will speedily be relieved by the release of medical officers from military service at the rate of some hundreds every month. The Professional Committees in Great Britain, which, with the able guidance of members of this Council, have so effectively aided the Government in recruiting for the medical services during the war, are coöperating with the authorities in solving the scarcely less difficult problems of demobilisation and resettlement. In particular, it has been arranged that the release of teachers in our medical schools and hospitals shall have special consideration. The influx of students returned from active service, with a view to the early completion of their professional course, makes it urgent that the sadly depleted staffs of skilled instructors should be reinforced without delay.

Sir Donald MacAlister then referred to the census of medical students which was completed in June, recapitulating the figures which have already appeared in our columns (THE LANCET, July 27th, p. 113, August 31st, p. 308). On the basis of these figures he had suggested to the Minister of National Service that, so far as the immediate requirements for junior students were concerned, it was unnecessary to extend beyond the original term—namely, July 31st, 1918—the instruction conferring exemption from military service on first-year men. This suggestion had been adopted. Sir Auckland Geddes had now, he added, become President of the Local Government Board, retaining the direction of the National Service Ministry for the present, and it was gratifying to the medical profession that during the period of transition and rebuilding the responsible administrator should be a registered medical practitioner of high distinction as a teacher and an organiser.

The number of newly qualified practitioners would this year be below the average, notwithstanding the steps taken to recall senior students from the Army to the medical schools. Somewhat tardy measures had been adopted to maintain the supply of senior dental students, but so far the qualified dentists added to the Dentists' Register had been few. The number attending the schools of dentistry with a view to qualification was also very small indeed. The prospect of a considerable addition to the ranks of qualified dentists, plainly required to meet immediate wants, was not encouraging. The Report of the Departmental Committee on the Dentists Act, which he had hoped might be before the Council this session, had not yet appeared. The problem the Committee was set to discuss did not become simpler with the rapid growth of the national demand for healthier conditions. A solution, Sir Donald MacAlister remarked, becomes every day more necessary.

Ministry of Health.—Other Legislative Measures.

Regarding the proposals for a Ministry of Health, he said:—

The Lord President has been moved to forward, for the observations of the Council, the text of a Bill which proposes to establish a Ministry of Health for England and Wales and a Board of Health for Scotland for the exercise of powers with respect to health and local government. The Bill has been read a first time in the House of Commons, but will not be further proceeded with until the new Parliament meets. I suggest that the Council should first consider *in camerâ* the manner in which it may with most advantage conduct the discussion of the Bill, with a view to formulating such observations thereon as it may wish to submit to the Lord President. The Bill, it will be found, is rather an enabling than an enacting measure. Certain medical functions of other departments are forthwith transferred to the new authority. Others may be transferred by Order in Council. Time will be given for the public discussion of such Orders before they take effect, and it is obvious that in many cases the terms of the Order may be of cardinal importance for medical science and practice. The Bill as it stands contains little that explicitly affects this Council, though I observe that it is made the duty of the Minister of Health to take steps for the effective carrying out of measures conducive to the health of the people, including "the training of persons engaged in health service." It should, I think, be made clear whether this phrase would or would not cover the functions exercisable by the Privy Council and this Council in relation to medical and dental education, to public health diplomas, to rules framed by the Central Midwives Boards, and the like. I am advised that it would not; but the Council will, no doubt, consider the point to be of some importance.

Other legislative measures were briefly alluded to:—

The Midwives Acts for Scotland and Ireland, passed during the war as urgently necessary in the public interest, have now been supplemented by an Act amending the English Act of 1902. The amendments tend to harmonise the three laws and to fill up lacunæ in the latter Act which experience of its administration had disclosed. In it provision is at length made for the remuneration of English practitioners called in to deal with emergencies arising in the practice of certified midwives. The Central Midwives Board for Ireland has framed rules for governing such practice in that country. The Privy Council, in accordance with the Irish Act and with the new English Act, has submitted the rules to the Executive Committee for comment. They follow, in the main, the pattern of the Scottish Board's rules, which have been already approved by the Council.

Certain Bills have been before Parliament dealing with the grave question of venereal disease and its prevention. A Joint Committee of both Houses has been considering them in their bearing on the important Act passed last year. You will remember that under its provisions the practice of unqualified persons professing to treat these diseases was legally prohibited in certain areas. The Bills in question propose to extend the prohibition to all parts of the country, and to impose penalties on unqualified persons who publicly advertise themselves as prepared to treat or to supply "cures" for this class of maladies. As your President I was asked to give evidence before the Committee, and testified to the various aspects of the matter brought to the notice of the Council by Dr. Langley Browne's Unqualified Practice Committee and otherwise; and to the enactments of the Overseas Dominions respecting unqualified practice in general, as extracted from the Council's minutes. Although the Bills will not proceed this session of the Council, I understand the evidence given will be printed, and that the Committee will probably be reconstituted and report to the next Parliament.

Examination in General Education.—Training in Preventive Medicine.

The President then went on to record the progress made by the English Board of Education with the elaboration of its scheme for a general school examination to take the place of the multiple examinations in general education with which teachers and scholars have too long been burdened. Dr. Mackay, on behalf of the Education Committee, is charged with a report on the subject. Meanwhile the four Scottish Universities had received from His Majesty in Council a new Ordinance which establishes a common Entrance Board, empowered to accept the leaving certificates of the Scotch Education Department as the normal qualification for admission to the universities in all faculties. This would liberate the Faculty of Medicine from the obligation, hitherto imposed upon it by Ordinance, to accept a lower standard of preliminary education than that required for degrees in arts or science. "I am," he said, "sanguine enough to believe that the so-called 'Junior' Preliminary Examinations for students of medicine will cease to be recognised in Scotland before they are extinct elsewhere." The large and indeed embarrassing affluence of students much below the age of 18 who were now entering the medical schools made the change more than ever expedient on educational grounds.

Training in preventive medicine had been considered during the recess by the members of the Education Committee, and proposals would be submitted. He called attention to the remarkable Memorandum on Medical Education in England, addressed to the President of the Board of Education by Sir George Newman, setting forth the changes that have gradually been made in the duties and responsibilities of the medical practitioner with

reference to public health and public administration, and the grounds for requiring that a corresponding change should be made in the manner and matter of his training for their fulfilment.

In forecasting the programme of the session Sir Donald MacAlister expressed gratification that complaints of laxity in granting certificates had practically ceased, a testimony to the efficacy of the warning notices issued.

Appointment of Officers.

The names of Mr. Robert Howden, Dr. David Hepburn, Sir Bertram C. A. Windle, Dr. N. P. Walker, Mr. H. J. Waring, Mr. J. W. B. Hodsdon, and Sir Arthur Chance were added to the Anatomy Acts Committee.

Dr. Norman Moore was appointed treasurer in succession to Sir Frederick Taylor, retired, and Dr. Norman Walker chairman of the Business Committee.

WEDNESDAY, NOV. 27TH.

The Council proceeded to the consideration of penal cases. At the conclusion of the sitting reports of the Public Health, Examination, and Education Committees were received and entered on the minutes, as well as a letter from the Privy Council asking for comment upon the Ministries of Health Bill, 1918.

URBAN VITAL STATISTICS.

VITAL STATISTICS OF LONDON DURING OCTOBER, 1918.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 5·9 per 1000 of the population, estimated at 4,026,901 persons; in the three preceding months the rates had been 3·5, 3·2, and 4·7 per 1000. Among the metropolitan boroughs the lowest rates from these notified diseases were recorded in Chelsea, the City of Westminster, St. Marylebone, Hampstead, and the City of London; and the highest rates in Hackney, Bethnal Green, Stepney, Southwark, and Bermondsey. The prevalence of scarlet fever was 60 per cent. higher than in the preceding month; this disease was proportionately most prevalent in Hammersmith, Shoreditch, Bethnal Green, Stepney, Southwark, and Bermondsey. The Metropolitan Asylums Hospitals contained 1184 scarlet fever patients at the end of the month, against 753, 690, and 931 at the end of the three preceding months; the weekly admissions averaged 178, against 105, 101, and 164 in the three preceding months. The prevalence of diphtheria was about 50 per cent. higher than in September; the greatest proportional prevalence of this disease was recorded in Stoke Newington, Hackney, Bethnal Green, Stepney, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 918, 886, and 1051 at the end of the three preceding months, had further increased to 1155 at the end of October; the weekly admissions averaged 169, against 122, 107, and 166 in the three preceding months. The prevalence of enteric fever was nearly double that in each of the two preceding months; of the 50 cases notified during October, 6 belonged to Islington, 6 to Deptford, 4 each to Bethnal Green and Hackney, and 3 each to Paddington, Kensington, Hammersmith, and Camberwell. There were 56 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 23, 32, and 43 at the end of the three preceding months; the weekly admissions averaged 9, against 6 in each of the two preceding months. Erysipelas was proportionally most prevalent in Islington, Hackney, Bethnal Green, Stepney, Southwark, Wandsworth, and Camberwell. The 12 cases of puerperal fever notified during the month included 3 in Southwark and 2 each in Shoreditch and Wandsworth. Of the 14 cases of cerebro-spinal meningitis 4 belonged to Stepney and 2 to Lewisham, and 4 of the 11 cases of poliomyelitis were notified in Islington.

The mortality statistics in the table relate to the deaths of civilians belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased had previously resided. During the five weeks ended Nov. 2nd the deaths of 10,559 London residents were registered, equal to an annual rate of 27·3 per 1000; in the three preceding months the rates had been 14·8, 10·1, and 11·4 per 1000. The death-rates ranged from 16·5 in Hampstead, 19·6 in the City of Westminster, 21·2 in Hammersmith, 21·3 in Chelsea, and 22·2 in Fulham, to 34·9 in Hackney, 35·0 in Stoke Newington, 35·8 in Battersea, 36·0 in Woolwich, and 38·2 in St. Pancras. The 10,559 deaths from all causes included 334 which were referred to the principal infectious diseases, and included 22 from measles, 24 from scarlet fever, 90 from diphtheria, 17 from whooping-cough, 10 from enteric fever, and 171 from infantile diarrhœa. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Chelsea, Hampstead, Finsbury, Wandsworth, and Lewisham; and the highest in Stoke Newington, Hackney, Bethnal Green, and Greenwich. The 22 deaths from measles were 27 below the average number in the corresponding period of the five preceding years, and included 6 in St. Pancras, 3 in Lewisham, and 2 each in St. Marylebone and Battersea. The 24 fatal cases of scarlet fever were 6 above the average, and included 6 belonging to Bethnal Green, 4 to Southwark, and 3 to Islington. The 90 deaths attributed to diphtheria were 18 in excess of the average, and included 22 in Hackney, 6 each to Stoke Newington, Stepney, Lambeth, Wandsworth, and Woolwich, and 5 to Southwark. The deaths from whooping-cough numbered 17, and showed a decline of 18 from the average; of these, 4 belonged to Camberwell and

* Including membranous croup.

3 to Islington. The 10 fatal cases of enteric fever were one less than the average number, and included 2 each in Islington, Holborn, and Greenwich. The 171 deaths from infantile diarrhœa were no fewer than 256 below the average; this disease was proportionately most fatal in Kensington, the City of Westminster, Shoreditch, Bethnal Green, Bermondsey, and Greenwich. In conclusion, it may be stated that the aggregate mortality from these principal infectious diseases in London during October was 45 per cent. below the average.

(Week ended Nov. 23rd, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 43·8 and 38·7 per 1000 in the two preceding weeks, further declined to 36·3 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 36·8 or 7·2 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 11·8 in Wallasey, 12·9 in Portsmouth, and 13·3 in Gloucester, to 71·1 in Walsall, 74·6 in Nottingham, 76·9 in Stockport, 78·8 in Dewsbury, and 80·7 in West Bromwich. The principal epidemic diseases caused 207 deaths, which corresponded to an annual rate of 0·7 per 1000, and included 60 from infantile diarrhœa, 53 from diphtheria, 44 from measles, 25 from whooping-cough, 18 from scarlet fever, and 7 from enteric fever. Whooping-cough caused a death-rate of 1·4 in Blackburn and 1·5 in Preston, and measles of 1·7 in Wolverhampton and 3·6 in Walsall. The deaths from influenza numbered 5106, against 5916 in the preceding week, and included 1178 in London, 311 in Manchester, 280 in Birmingham, 207 in Nottingham, 164 in Sheffield, 163 in Leeds, and 121 in Bradford. The 1149 cases of scarlet fever and 1062 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 22 and 24 below the respective numbers remaining at the end of the previous week. The causes of 96 deaths in the 96 towns were uncertified, of which 17 were registered in Birmingham, 13 in Nottingham, 8 in South Shields, and 6 in West Bromwich.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 24·3 per 1000, against 27·0 and 23·9 per 1000 in the two preceding weeks. Of the 1121 deaths from all causes, 29 were classified to influenza, which was also stated as a contributory cause in 252 deaths classified to other diseases; in the previous week these numbers were 46 and 331 respectively. The 502 deaths in Glasgow corresponded to an annual rate of 23·5 per 1000, and included 7 from diphtheria, 6 from whooping-cough, 4 from infantile diarrhœa, and 1 from scarlet fever. The 208 deaths in Edinburgh were equal to a rate of 32·5 per 1000, and included 5 from whooping-cough, 2 each from scarlet fever and infantile diarrhœa, and 1 from diphtheria.

Irish Towns.—The 244 deaths in Dublin corresponded to an annual rate of 31·9, or 13·7 per 1000 below that recorded in the previous week, and included 67 from influenza and 1 from infantile diarrhœa. The 490 deaths in Belfast were equal to a rate of 65·0 per 1000, and included 2 from infantile diarrhœa.

EDITORIAL NOTICE.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Communications, Letters, &c., to the Editor have been received from—

A.—Capt. G. K. Aubrey, late R.A.M.C.; Mr. J. H. Allan, Liverpool; Col. J. G. Adami, A.D.M.S.; Miss Lena Ashwell, Lond.; Messrs. Allen and Hanburys, Lond.

Births, Marriages, and Deaths.

BIRTHS

CHARTRES.—On Nov. 24th, at Dodbrook Manor, Devon, the wife of Lieutenant-Colonel E. Acheson Chartres, R.A.M.C., of a son.

HARE.—On Nov. 23rd, at Cheltenham, the wife of Captain (acting Major) W. T. Hare, M.C., R.A.M.C., of a son.

SMITH.—On Nov. 24th, at Queen's-drive, Mossley-hill, Liverpool, the wife of Captain George F. R. Smith, R.A.M.C. (T.F.), of a daughter.

WOODSEND.—On Nov. 21st, at East Bridgeford Manor, Notts, the wife of R. N. Woodsend, M.B., B.S., Catterick, Yorks, Captain, R.A.M.C., of a son.

MARRIAGES.

HUGHES—MAINWARING.—On Nov. 23rd, at St. Clement Danes Church, London, Captain Frank Mainwaring Hughes, R.A.M.C. (T.F.) (Legion d'Honneur, Croix de Chevalier), to Mary, elder daughter of Mr. and Mrs. Frederick Hope Mainwaring, of Northfleet, Kent.

LARGE—COWAN.—On Nov. 25th, at St. Paul's Church, Edinburgh, Lieutenant-Colonel Stanley Dermott Large, D.S.O., M.C., R.A.M.C., to Violet Muriel Elise (Mona), youngest daughter of David Cowan, Esq., J.P., M.Inst.C.E., of Coulport, Cove, Dumbartonshire, and Abernethy, Perthshire.

PETERS—BENNETT.—On Nov. 21st, at St. John's Church, Cambridge-square, W., by the Rev. H. F. S. Adams, vicar, Haydn Peters, Captain, R.A.M.C., to Violet Mona, daughter of the late Mr. Justice T. R. Bennett, of Pietermaritzburg, Natal. South African papers please copy.

DEATHS.

GARDINER.—On Nov. 20th, at Mount Adon Park, Lordship-lane, Dulwich, Bruce Hubert John Gordiner, M.D.

HOPE.—On Nov. 21st, at Fernley Hotel, Bath, from pneumonia contracted when doing National Service work, James William Hope, F.R.C.P. Edin., D.P.H., late Principal Medical Officer and Commissioner of Public Health, Western Australia.

JAMES.—On Nov. 16th, at Upper Holloway, London, of pneumonia following influenza, M. B. James, M.B., Ch.B., aged 49 years.

MILES.—On Nov. 25th, at Pinfold-road, Streatham, S.W., of pneumonia following influenza, Maurice W. Holt Miles, Captain, R.A.M.C. (late), S.R., aged 25.

O'REILLY.—On Nov. 18th, at Holmwood, North Park, Eltham, Lieutenant-Colonel P. S. O'Reilly, C.M.G., R.A.M.C., aged 41 years.

REID.—On Nov. 18th, suddenly, James More Reid, Lieutenant-Colonel, R.A.M.C., aged 62.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.1.

MEETINGS OF SECTIONS.

Tuesday, Dec. 3rd.

PATHOLOGY (Hon. Secretaries—Gordon W. Goodhart, J. A. Murray): at 5.30 P.M.

Discussion on "The Pathology of Gas Gangrene."

It is hoped that the following will speak:—Prof. Weinberg (Paris), Major J. W. McNee, Dr. McIntosh, Dr. Henry, and Dr. Bulloch.

Wednesday, Dec. 4th.

SURGERY (Hon. Secretaries—V. Warren Low, Cyril A. R. Nitch): at 5.30 P.M.

Papers:

Lieut.-Col. Percy Sargent, D.S.O., R.A.M.C.: The Closure of Cavities in Bone.

To be followed by a discussion in which the following gentlemen will take part:—Major Oswald Shields, R.A.M.C., Capt. Simmonds, R.A.M.C., Mr. E. Gillespie, F.R.C.S., Capt. Z. Mennell, R.A.M.C.(T.)

Major John Robert Lee, M.D., B.S., R.A.M.C.: Compound Fractures of the Femur in its Upper Third, and demonstration of new Thigh and Arm Splints.

Thursday, Dec. 5th.

OBSTETRICS AND GYNÆCOLOGY (Hon. Secretaries—Comyns Berkeley, J. S. Fairbairn): at 8 P.M.

Short Communications:

Dr. Drummond Robinson: A Case of Paraplegia in a Pregnant Woman.

Mr. Clifford White: On Sections of Kidney removed by Operation from Two Cases of Puerperal Suppression of Urine.

Specimens will be shown by—

The President (Mr. J. D. Malcolm): An Unusual Concretion in a Fibroid.

Dr. Drummond Robinson: (1) A Skiagram of Foreign Body in the Gravid Uterus; (2) Uterus showing changes taking place as the result of Procidentia.

Mr. T. G. Stevens: Foreign Bodies in the Bladder.

Friday, Dec. 6th.

LARYNGOLOGY (Hon. Secretaries—Frank A. Rose, Irwin Moore): at 4 P.M.

Discussion on "Dilatation of the Œsophagus without Anatomical Stenosis," to be opened by Dr. Brown Kelly and Dr. William Hill.

ANÆSTHETICS.

Discussion on "The Present Position of Spinal Anæsthesia," to be opened by Dr. F. S. Rood.

N.B.—A résumé of Dr. Rood's paper will be in the Library for reference a week before the meeting.

Will Members please note that abstracts of papers to be read at meetings are placed in the Library for reference a week before the meeting at which they are to be read.

SURGERY.—Members of the Section of Surgery are specially invited to attend the above discussion.

The Royal Society of Medicine keeps open house for R.A.M.C. men and M.O.'s of the Dominions and Allies. The principal hospitals in the metropolis admit medical officers to their operations, lectures, &c. Particulars on application to the Secretary at 1, Wimpole-street, London, W. 1.

MEDICAL SOCIETY OF LONDON, 11, Chandos-st., Cavendish-sq., W.

MONDAY, Dec. 2nd.—8.30 P.M., Discussion on Reconstruction in Medical Education and Practice, to be introduced by Col. H. J. Waring, R.A.M.C.(T.)

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY, Dec. 4th.—4.30 P.M., Paper:—Mr. B. S. Rowntree: Housing after the War.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, Dec. 2nd.—2 P.M., Medical and Surgical Clinics. X Rays Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

THURSDAY, Dec. 5th.—5 P.M., Chesterfield Lecture:—Dr. M. Dockrell: The Papular Eruptions.

ROYAL INSTITUTE OF PUBLIC HEALTH, in the Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures on Public Health Problems under War and After-war Conditions (each Lecture will be followed by a Discussion):—

WEDNESDAY, Dec. 4th.—4 P.M., Lecture IX.:—Prof. E. W. Hope: The Rôle of the Ports in the Protection of the Health of the Nation.

Notes, Short Comments, and Answers to Correspondents.

THE CARE OF THE DISABLED.

Sir John Collie was to have read a paper on the care of pensioners and disabled combatants in relation to national health and wealth at the Royal Institute of Public Health on Nov. 21st, with Mr. John Hodge in the chair. Neither was able to keep his engagement, and the paper was read in truncated form by Major Basil Rhodes, who indicated the magnitude of the task before the Ministry, since 70,000 surgical and medical cases had already passed through its hands. But wounds and injuries, Sir John Collie said, did not constitute the chief difficulty, which lay in the mental effects of their injuries upon the pensioners. On the credit side of the nation's account, however, must be set the improvement in physique of men who but for military training would have been stunted in growth. It was obviously the duty of the nation to provide an adequate medical service for men who had risked life and health for their country, but it was proving very difficult to keep pace with their requirements. The paper laid stress on the need for the adequate treatment of neurasthenic and shell shock cases, for spinal injuries, and orthopædic cases in general, and for the tuberculous.

COLONIAL HEALTH REPORTS.

Weihaiwei.—In his report for 1917, recently received at the Colonial Office, Mr. R. F. Johnston, Administrator, writes:—

There were very few cases of epidemic disease in the Territory, which maintains its reputation as one of the healthiest districts on the coast of China. A considerable number of cases of dysentery occurred among both Europeans and Chinese, and although it is true that some of these cases were among non-residents who had been attacked by the disease before their arrival in Weihaiwei, there is reason to believe that the outbreak is to some extent traceable to unsatisfactory sanitary conditions both on the mainland and on the island. Steps are being taken to remedy these. ..... I am at present drawing up a scheme for the introduction into the island of market gardening and fruit culture on a fairly large scale. It is proposed to lease garden-lots to approved tenants on very stringent conditions, whereby the Government sanitary authorities will be enabled to exercise strict control over the methods of cultivation, and thereby ensure that the local market will be provided with regular and ample supplies of sound fruit and vegetables. Those who know how readily disease is conveyed in China through the medium of vegetable produce grown and retailed under insanitary conditions will realise the enormous benefit that the proper working of the proposed scheme will confer upon residents in Weihaiwei.

It was feared that the opening of the War Office Labour Depôt would be detrimental to the health of the territory, especially as it was known that the very advantageous terms offered by the British Government would attract large numbers of underfed coolies from those districts of Chili which, as a result of the great floods, were stricken by both famine and disease. It is satisfactory to report, however, that the health statistics of the territory seem to have been in no way affected by the influx of labourers. Much credit for this is due to the depôt authorities who successfully isolated all cases of contagious disease within the limits of the depôt itself. In the hospital at Port Edward 7572 out-patients and 253 in-patients were treated, and the number of operations performed was 258. In the new hospital at Wen-ch'uan-t'ang 2749 new cases were treated and the total number of attendances was 4715. At the Island Hospital there were 5193 attendances, as compared with 6225 in 1916. The decrease in the number of patients is due to the dwindling of the population. The island has long ceased to be the commercial centre of the territory, and the majority of the inhabitants have migrated to the mainland. Opium-smoking in the Territory is forbidden under legal penalties. The only persons who are allowed to consume the drug in any form are those who have been given licences to do so after examination by a Government medical officer. At the end of 1917 there were 46 licensed smokers, but there is not the least doubt that the number of opium-smokers is much larger than the number of licence-holders would indicate. The highest temperature recorded in 1917 was 95° F. in June, the lowest 8° F. in January. Rain or snow fell on 73 days, the fall for the year being 33·28 inches; the average rainfall for 17 years has been 28·38 inches.

LAMED.

To the Editor of THE LANCET.

SIR,—There must be many, like myself, with good arms and one good leg. I should feel much obliged if any of your readers can say where a really good self-propelled venicle can be procured which can be worked by the three limbs mentioned. Of course, it must be able to climb moderate hills to be of much use.—I am, Sir, yours faithfully,

Nov. 22nd, 1918. "LAMED."

WOMEN AND A MINISTRY OF HEALTH.

AT a public meeting organised by the National Baby Week Council, and held at the Armitage Hall on Nov. 25th, Lady Barrett, M.D., proposed a resolution to the effect—

That the organised services of women should be secured for the Ministry of Health as civil servants in the Ministry and in an advisory capacity, and a direct channel of communication between the women in the homes and the Ministry should be established.

We should, she contended, have no great results from such a Ministry unless based upon the needs of those most concerned in its operations. Schemes for a complete midwifery or antenatal service drawn up without the aid of women would end in failure. Proper recreation must be provided in the home. The manifestations of joy are the manifestations of health; mothers especially required real joy in their lives, and its realisation required the coöperation of men and women. The spread of venereal disease among girls of 13 to 16 years Lady Barrett attributed in large measure to faulty training and bad environment; here again the need was for more joy in their lives. On the advisory councils of the Ministry women should have large representation, while some of the executive officers at headquarters should be women. The resolution was passed unanimously.

PRECAUTIONS AGAINST INFLUENZA IN FRENCH SCHOOLS.

THE Prefect of the Seine, on the advice of various hygienic authorities, has issued for the guidance of directors of schools in Paris and the contiguous departments the following scheme of measures for dealing with the influenza epidemic:—

1° Supprimer toutes les réunions dans les locaux scolaires.

2° Faire procéder à des enquêtes par les soins des directeurs et directrices sur les motifs d'absence des élèves; transmettre sans retard, au secrétariat de l'inspection médicale des écoles, les résultats de ces enquêtes; éliminer, lors de la visite quotidienne de propreté, tout enfant qui paraîtra présenter des symptômes d'indisposition et le faire reconduire à sa famille en conseillant à celle-ci de recourir sans aucun retard à un médecin.

3° Conseiller aux familles de garder chez elles leurs enfants lorsqu'ils paraissent souffrants.

4° Evincer les frères et sœurs des malades. A cet effet, les directeurs et directrices doivent prévenir leurs collègues des écoles fréquentées par ces frères et sœurs chaque fois que des élèves de leurs propres établissements leur sont signalés comme atteints de grippe.

5° Faire pratiquer des lavages fréquents des parquets et tables de classe à l'aide d'une solution à base soit d'eau de javel, soit de créoline, soit de formol ou d'anodorine.

6° Ne pas licencier les écoles en totalité, mais licencier pour une quinzaine de jours toute classe dans laquelle les trois quarts des élèves sont absents pour cause de grippe; toutefois, il appartient aux médecins inspecteurs des écoles de proposer *exceptionnellement* le licenciement dans les cas qui leur paraîtront particulièrement graves.

7° Conseiller l'antisepsie des fosses nasales à l'aide de quelques gouttes d'huile de vaseline goménolée ou d'une solution au collargol.

Gomenol, it may be added, is a proprietary French remedy, stated to be obtained from a plant of the myrtle tribe, and taking the place of such familiar preparations as menthol and eucalyptol.

BOOKS FOR REFERENCE.

Burdett's Hospitals and Charities, 1918, being the Year Book of Philanthropy and the Hospital Annual, which has just made its twenty-ninth appearance (London: The Scientific Press. Pp. 922. 12*s.* 6*d.* net), maintains its record for accuracy and convenience of reference, though the index is still vexatiously placed in the middle instead of at one or other end of the book. The title-page states quite truthfully that the book is an exhaustive record of hospital work for the year. Owing to accident on the high seas the matter relating to hospitals in the Dominions has been perforce omitted.——*The Annual Charities Register and Digest, 1918* (London: Longmans, Green, and Co. Pp. 626. 5*s.* net), contains the usual lists of charities with particulars of their object, management, income, and the like, while short practical introductions to particular branches of charitable work have been added.——*Low's Handbook to the Charities of London, 1918* (London: Sampson Low, Marston, and Co. Pp. 254. 1*s.* 6*d.*), now in its eighty-third year of publication, retains its character as a brief and excellent alphabetical list of metropolitan charities, giving information as to their objects, date of formation, income, expenditure, address, and names of secretaries. The National Society for the Prevention of Cruelty to Children comes in for eulogy in the introduction.——The thirteenth issue of *The Girls' School Year Book, 1918*, the official reference book of the Association of Head Mistresses (London: The Year Book Press. Pp. 638. 6*s.* net), contains an alphabetical list of public schools for girls in Great Britain, along with full particulars of the staffs, fees, terms of admission, and scholarships; also an account of possible careers for girls, including those opened by the war, such as engineering and the cultivation of medicinal herbs. Special articles deal, among other subjects, with medical education, dentistry, pharmacy, nursing, sanitary inspection, and social and philanthropic work.

MINOR SURGERY IN THE FORECASTLE.

THIS is the captain's story. Surgery at sea, in the forecastle of a sailing ship, has its routine of practice, just as you have yours in the profession. Assume a sailor develops a boil. For the first two or three days it is subjected to the interested examination of the other sailors, who sit in committee on it to advise whether it is an abscess or a boil, or what; and the treatment is discussed at great length, the various consultants advising the patient to take pitch pills for it, or to put on hot fomentations, with long discussions as to the value of each treatment in the experience of those present. But at last it appears that further measures must be taken; it is necessary to open the boil. The opening is a procedure of the highest interest to everybody. It is done with a sheath knife, held half an inch from the point to prevent mischief, and the boil is opened with a long incision. A bit of rope is then unlaid (untwisted), and a couple of strands are arranged one on each side of the swelling, and they are twisted together at each end, compressing the swelling, and forcing out of the boil the core, about which everyone is expectant. The treatment is, you observe, properly antiseptic, and by the gradual twisting together of the strands the core is squeezed out and then removed in the loop of the strand. As for further treatment there is probably none, and the place heals up, but sometimes a drop of coal-tar is put in the cavity, and that has the advantage of giving the patient great pain, and assuring him that everything possible has been done by his skilful shipmates to secure his recovery.

THE INTRAMUSCULAR INJECTION OF MERCURIC CHLORIDE IN INFLUENZA.

Messrs. Allen and Hanburys have drawn our attention to an important point in regard to the use of an intramuscular injection of perchloride of mercury in the alleged successful treatment of influenza reported in the *Times* of Nov. 26th. The *Times* correspondent, writing from Athens, states "that the treatment consisted of intramuscular injections of 3 in 100 of the following solution: perchloride of mercury, chlorate of sodium, and distilled water." If this means a 3 per cent. solution of the mercuric salt (which may not necessarily be the case), then 1 minim would contain the maximum dose of corrosive sublimate, namely, 1/30 gr. The intramuscular injection of 1/60 to 1/30 gr. of mercuric chloride is a well-known measure. Possibly the action of the mercuric salt may be modified by the addition of an oxidant like chlorate of sodium. The formula as given is vague and no attempt to follow it should be made until clearer details are to hand.

FUEL ECONOMY.

THE continued shortage of fuel makes timely the reprint of the series of lectures delivered in the Department of Heating and Ventilating at University College, London, during the session 1918. These lectures on Fuel Economy and Cooking Apparatus, by Mr. A. H. Barker, B.Sc., reprinted in pamphlet form from the *Builder* (4, Catherine-street, Aldwych, W.C. 2, price 1*s.* 6*d.*), lay down the general principles on which it is hoped improvements in economy of fuel may be effected. Diagrams illustrate various forms of economical and wasteful stoves, while the questions of efficiency and cost are graphically set out where desirable. The pamphlet may be read with advantage as an introduction to the Fuel Economy Exhibition now showing in Trafalgar-square, London.

ROYAL INSTITUTION THE CHRISTMAS COURSE OF JUVENILE LECTURES.

THE ninety-third illustrated Christmas Course of Juvenile Lectures, founded at the Royal Institution in 1826 by Michael Faraday, will be delivered this year by Professor D'Arcy Thompson, C.B., F.R.S., his title being "The Fish of the Sea." The subjects are as follows: Jelly-fishes, Tuesday, Dec. 31st; Star-fishes, Thursday, Jan. 2nd; Cray-fishes, Saturday, Jan. 4; Cuttle-fishes, Tuesday, Jan. 7th; The Herring Fishery, Thursday, Jan. 9th; The Whale Fishery, Saturday, Jan. 11th. The lecture hour is 3 P.M.

FALCONER'S ARTHROMETER.

Dr. Charles F. Sonntag writes from the Special Military Surgical Hospital, Shepherd's Bush, in regard to the figures printed on the arthrometer illustrated on p. 632 of THE LANCET of Nov. 9th—viz., "knee-joint, 120°; elbow-joint, 140°." These figures cannot be intended to represent the full range of normal movement of these joints. Dr. Sonntag has measured the range of movement of his own knee-joint and finds it to be 158°. We learn from Dr. Fortescue Fox that the measurements of knee movement at the Red Cross Clinic are taken with the patient lying *prone* on the couch—that is to say, with the hip extended. Simultaneous flexion at the hip allows of relaxation of the extensors of the knee, when an additional 20° knee-flexion can be obtained. Dr. Fox adds that in recording measurements the posture should always be stated.

An Experimental Study OF THE INFLUENCE OF DIET ON TEETH FORMATION.

BY MAY MELLANBY,

FROM THE HOUSEHOLD AND SOCIAL SCIENCE DEPARTMENT OF THE LONDON UNIVERSITY, KENSINGTON.

(*Preliminary Report to the Medical Research Committee.*)

THE misery caused, both directly and indirectly, by unsound teeth is too well known to the medical profession and to the general public to need emphasis. The fact that dentistry plays such an important part in civilised communities to-day proves that the problem needs the further attention of medical research.

The majority of investigations so far carried out have dealt with the etiology of caries. The type of food, considered from the point of view of its hardness and softness, its liability to undergo bacterial decomposition with the production of acids, toxins, &c., has completely dominated the picture.

VIEWS ON ETIOLOGY OF DENTAL HYPOPLASIA.

The etiology of hypoplasia has received less attention. Several suggestions have, however, been put forward to account for the imperfect development of teeth. A particular defect of certain teeth has been associated with congenital syphilis; the exact method by which it is produced has not been demonstrated. Other types of hypoplasia, characterised by one or more bands of defective enamel, have been traced to one of the specific fevers or to some other acute illness. As regards the more generalised types of gross hypoplasia, the parts of the teeth usually affected point to some cause acting during the first two years or so of life. The association with infant feeding is obvious, but here again it is not known whether the results are due to insufficient food, diet of an unsuitable kind, the assimilation of harmful products, or intestinal disturbances set up by abnormal fermentative processes reacting on the trophic control of calcification.

Apart from these gross forms of hypoplasia, there is little doubt that marked differences exist in the degree of hardness of the enamel, the physical structure, and the perfection of calcification. The so-called "mottled teeth" exhibit in their partial lack of translucency such slight forms of hypoplasia. Between this and perfect enamel there must be many grades. Another hypothesis that also needs further investigation is that defective calcification is due to a deficiency of calcium salts in the diet.

SCOPE OF PRESENT INVESTIGATION.

The investigation to be described in this paper was undertaken primarily with the object of studying—

(1) The factors involved in the development of sound teeth and of the growth of the jaws in relation to the size of the teeth.

(2) The factors bearing on the immunity of erupted teeth to caries and other diseases.

In this preliminary paper I propose to describe experimental work which deals with the first of the above problems and will adduce evidence to show that—

(1) Hypoplasia of the teeth is caused largely by a deficient diet.

(2) The factor in the diet which controls the calcification of the teeth is something of the nature of an accessory food factor (vitamine).

(3) This factor has a similar distribution to that of fat-soluble A, and has recently been shown by E. Mellanby to be largely responsible for the calcification of bone, a deficiency of this substance in the diet being followed by the development of rickets.

Experiments dealing with conditions affecting the teeth after eruption are in progress, but it will be agreed that this question is, in many ways, of secondary importance; for if the enamel on all parts of the crowns of teeth is abundant and sound, and if the teeth are adequately spaced, then such teeth are less likely to be attacked by caries and other diseases.

The part of this work to be described here has involved the examination of the teeth of those puppies used by my husband, Dr. Edward Mellanby,[1] in the course of an extensive research on rickets made for the Medical Research Committee. Details of the diets will be found in a paper to be published immediately by him. Suffice it here to say that the diets consisted chiefly of white bread and separated milk, about 200 c.cm. per diem, together with the substances to be tested.

For work of this nature domesticated dogs are eminently suitable, in the first place because their normal diet is very similar to that of man, and in the second place because the formation and development of their teeth is more comparable with his than is the case with most other available animals.

In examining the jaws and teeth attention has been paid to the study of (1) the time of shedding of the deciduous teeth; (2) the time of eruption of the permanent dentition; (3) the arrangement of the teeth in the jaws; (4) the condition of the enamel, &c.; (5) the calcium content of the teeth.

RESULTS OF EXPERIMENTS.

Fig. 1 represents the lower jaws of three puppies of the same litter. When approximately 8 weeks old they were put on to diets the only differences in which were that (*a*) contained 10 g. of cod-liver oil per diem, (*b*) 10 g. of butter, and (*c*) 10 g. of linseed oil. The puppies were killed 15 weeks after the diets were started. It will be observed that (*a*) has lost all its deciduous teeth, while all the permanent teeth are fully developed; (*b*) comes next in order—here some of the deciduous teeth are still firm in the jaws, while the permanent teeth are not all erupted; (*c*) is still further behind, both as regards the shedding of the deciduous and the eruption of the permanent teeth. The arrangement of the teeth in the jaws is also better in (*a*) and (*b*) than in (*c*). The condition of the enamel varies in each case, appearing perfect in (*a*), slightly defective in places in (*b*), while in (*c*) the enamel on that part of the crown near the neck of the incisors is dark brown and that on the carnassials, except the top of the cusps, is dull brown. (See also Fig. 3, 145(*c*).)

Formula Used in Description.

$i^{1\,2\,3} \times 2$ indicates 1st, 2nd, and 3rd incisors of both sides.
$c \times 2$,, canines on ,, ,,
$pm^{1\,2\,3} \times 2$,, 1st, 2nd, and 3rd premolars ,, ,,
$m^{1\,2} \times 2$,, 1st and 2nd molars on both sides.
A line below letters means that letters refer to upper jaw.
,, above ,, ,, ,, lower ,,
(L) and (R) before letters indicate left and right respectively. After letters (j) = just, (n) = nearly.
($\frac{1}{2}$), ($\frac{1}{4}$), &c., after letters indicate that teeth are half and a quarter erupted, &c.
Thus $\underline{i \times 2}$ ($\frac{1}{2}$) = both 1st upper incisors half erupted.

Dentition in dogs:—

(a) *Deciduous.*

$$\frac{i\,3,\ c\,1,\ pm\,3}{i\,3,\ c\,1,\ pm\,3} \times 2 = 28.$$

(b) *Permanent.*

$$\frac{i\,3,\ c\,1,\ pm\,4,\ m\,2}{i\,3,\ c\,1,\ pm\,4,\ m\,3} \times 2 = 42.$$

The 4th upper premolars and the 1st lower molars are modified in carnivores to form the carnassials.

Detailed Notes on Teeth of Puppies (a), (b), (c), (d), (e), (f).

1. *Deciduous Teeth Still Retained.*

(*a*) None.

(*b*) $\dfrac{c \times 2}{(L)\ c,\ pm^{\,1} \times 2}$

(*c*) $\dfrac{c \times 2,\ pm^{\,2\,3} \times 2}{(R)\ c,\ pm^{\,1\,2\,3} \times 2}$

(*d*) $\dfrac{(L)\ i^{\,3},\ c \times 2,\ pm^{\,1\,2\,3} \times 2}{c \times 2,\ pm^{\,1\,2\,3} \times 2}$

(*e*) $\dfrac{i^{\,2} \times 2,\ c \times 2,\ pm^{\,2\,3} \times 2}{(L)\ i^{\,3},\ c \times 2,\ pm^{\,1\,2\,3} \times 2}$

(*f*) $\dfrac{i^{\,3} \times 2,\ (L)\ pm^{\,3}\ *}{c \times 2,\ pm^{\,3} \times 2\ *}$

* Very loose, knocked off before photo taken.

2. *Permanent Teeth Erupted.*

(*a*) $\dfrac{\text{all}}{\text{all except } m^{\,3} \times 2}$

(*b*) $\dfrac{i^{\,1\,2\,3} \times 2,\ c \times 2\ (\frac{1}{2}),\ pm^{\,1\,2\,3} \times 2\ (j),\ carn. \times 2\ (\frac{3}{4}),\ m^{\,1} \times 2\ (\frac{3}{4}),\ m^{2} \times 2\ (n)}{i^{\,1\,2\,3} \times 2,\ c \times 2\ (\frac{3}{4}),\ pm^{\,1\,2\,3} \times 2\ (j),\ pm^{\,4} \times 2\ (\frac{1}{2}),\ carn. \times 2,\ m^{\,2} \times 2\ (j)}$

(*c*) $\dfrac{i^{\,1\,2\,3} \times 2,\ c \times 2\ (\frac{1}{2}),\ pm^{\,1} \times 2\ (j),\ carn. \times 2\ (\frac{1}{2}),\ m^{\,1} \times 2\ (\frac{1}{2})}{i^{\,1\,2\,3} \times 2,\ c \times 2\ (\frac{1}{2}),\ carn. \times 2,\ m^{\,2} \times 2}$

(*d*) $\dfrac{i^{\,1\,2} \times 2,\ i^{\,3} \times 2\ (\frac{1}{2}),\ pm^{\,1} \times 2\ (j),\ m^{\,1\,2} \times 2\ (\frac{1}{2})}{i^{\,1\,2} \times 2,\ i^{\,3} \times 2\ (j),\ pm^{\,1} \times 2\ (n),\ carn. \times 2,\ m^{\,2} \times 2}$

(*e*) $\dfrac{i^{\,1} \times 2,\ i^{\,2\,3} \times 2\ (n),\ pm^{\,1} \times 2,\ (R)\ m^{\,1}\ (\frac{1}{4}),\ (L)\ m^{\,1}\ (j)}{i^{\,1} \times 2,\ (L)\ i^{\,2}\ (j),\ (R)\ i^{\,2},\ pm^{\,1} \times 2\ (j),\ carn. \times 2}$

(*f*) $\dfrac{i^{\,1\,2} \times 2,\ (L)\ pm^{\,2}\ (n),\ (R)\ pm^{\,2}\ (j),\ pm^{\,3} \times 2\ (j),\ carn. \times 2\ (\frac{1}{4}),\ m^{\,1} \times 2\ (\frac{1}{2})}{(L)\ i^{\,1},\ (R)\ i^{\,1}\ (\frac{1}{2}),\ (L)\ i^{\,2}\ (\frac{1}{4}),\ (R)\ i^{\,2}\ (n),\ pm^{\,1} \times 2\ (n),\ pm^{\,23}\ (j),\ carn. \times 2,\ m^{\,2} \times 2}$

3. *Arrangement of Teeth in Jaws.*

(*a*) and (*b*) Normal.
(*c*) Lower incisors irregular and somewhat crowded together.
(*d*), (*e*), and (*f*) Upper incisors fairly regular, but lower ones—(*f*) very—irregular and crowded.

[1] Journ. of Physiol., January, 1918.

4. *Condition of Enamel of Permanent Teeth.*

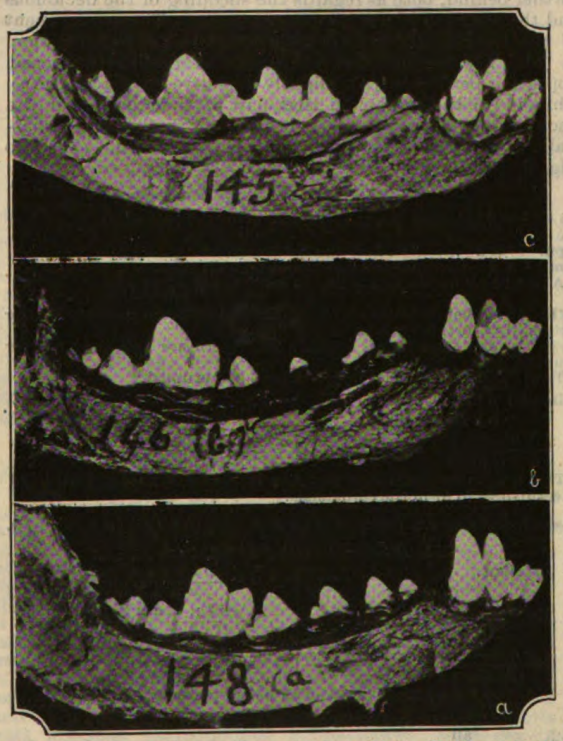
(*a*) White and shiny.
(*b*) On whole white and shiny; back teeth very slightly yellow.
(*c*) Dark brown colouring on that part of incisors near neck, especially of upper incisors; enamel on greater part of carnassials and first molars dull brown.
(*d*) The enamel does not appear very good on any of the teeth, but it is especially defective on first incisors and first molars of upper jaw and on that part of lower carn. near neck.
(*e*) The enamel fairly good on all permanent teeth.
(*f*) The enamel on all the teeth is very defective, except perhaps on tips of some of the cusps.

These experiments and others of the same type show that when linseed oil is the only fat in the diet, then there is a delay in the shedding of the deciduous teeth and in the development of the permanent dentition. The animal fats, and more particularly cod-liver oil, cause these changes to proceed in a normal way. Again, the arrangement of the teeth and their appearance is much better when animal fats have been eaten.

CONSIDERATION OF POSSIBLE INFLUENCE OF ILL-HEALTH.

A criticism to be met in this type of work is that any condition of ill-health during the period of the experiment may have been responsible for the changes described. It is true that these puppies suffered from mild attacks of distemper and that none of them grew very rapidly (on the average 2 kg. in the 15 weeks). Their periods of mild illness and their rates of growth were, however, practically speaking, identical, and could, therefore, not be the cause of the variations observed in the dentition.

FIG. 1.—*Age at Death about 5 Months 3 Weeks.*



(*a*) 1 g. cod-liver oil per diem added to diet; (*b*) 10 g. butter; (*c*) 10 g. linseed oil. All deciduous teeth of (*a*) shed, some remaining in (*b*), but most left in (*c*). Permanent teeth more fully erupted in (*a*) than in (*b*) and in (*b*) than in (*c*). Enamel in (*c*), especially near neck of incisors and the carnassials, is not nearly as good as in either (*a*) or (*b*).

In order to meet such a criticism in a more thorough way I will consider another set of experiments, illustrated in Fig. 2. Here again the lower jaws of three puppies—(*d*), (*e*), and (*f*)—of the same litter are shown. They are a larger breed of dog than those shown in Fig. 1. The puppies were in this case also about 8 weeks old when the experiment, which lasted 15 weeks, was started. The source of fat in each case was 10 g. of linseed oil per diem. Their relative rates of growth in the 15 weeks can be seen in the following table:—

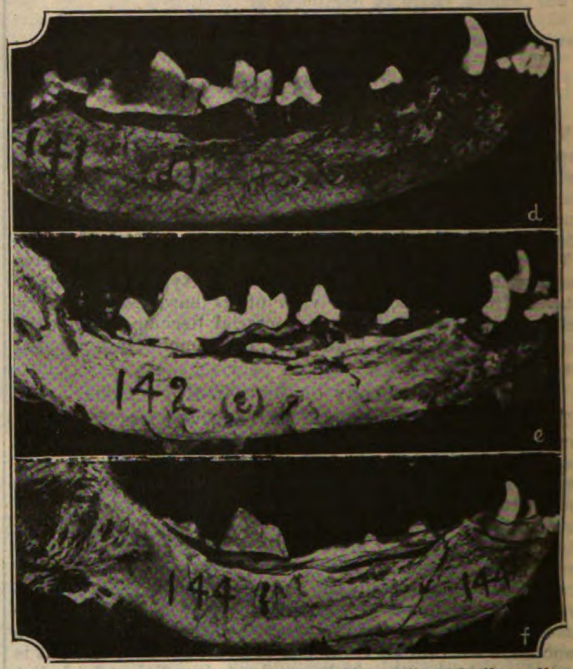
TABLE I.

	Wt. at beginning.	Wt. at end.	Increase.
(*d*)	2490 g.	5820 g.	3330 g.
(*e*)	2675	6820	4145
(*f*)	3690	8825	5135

It must be stated here that although (*e*) was on the same articles of diet as (*d*) and (*f*) for 6½ weeks, yet, from this time until the end of the experiment, 10 g. of butter were given daily in addition to the linseed oil.

It will be seen that all the teeth in Fig. 2 are delayed, not so much in the loss of the deciduous teeth as in the

FIG. 2.—*Age at Death about 5 Months 3 Weeks.*



The diets of (*d*), (*e*), and (*f*) all contained 10 g. of linseed oil per diem. (*e*) had in addition 10 g. of butter from 7th to 15th weeks. The majority of the deciduous teeth in (*f*) have been shed ($pm^3 \times 2$ knocked out before photograph taken), but the permanent ones are very delayed. The enamel on most of the teeth of these dogs is poor, especially in the case of (*f*), it is best in (*e*). The size of the jaw in the case of (*f*) is in reality greater than is the case in (*d*) and (*e*). The magnification is not so great in this photograph.

complete eruption of the secondary dentition. More striking still is the amount of defective enamel. In (*f*) there is hardly any white enamel, and that present is so soft that it can be cut with a scalpel. There is considerable irregularity in the setting of the teeth, especially in (*f*). In fact, the teeth of (*f*), the most rapidly growing puppy, are in every way worse than those of (*d*). In (*e*) the bad effects of the diet have been saved to some extent by the addition of butter after the first few weeks. Then, again, the teeth of (*d*) are distinctly worse than those of (*e*), which grew comparatively slowly.

As a general rule, it is difficult to associate rapid growth with ill-health, and yet we have seen in these experiments that the teeth of the more rapidly growing puppies are worse, whether the comparison is confined to the same or to another family. It seems impossible, therefore, to escape the conclusion that the malformed teeth are the result of some specific influence of the diet, such as has been suggested.

CALCIUM CONTENT OF TEETH.

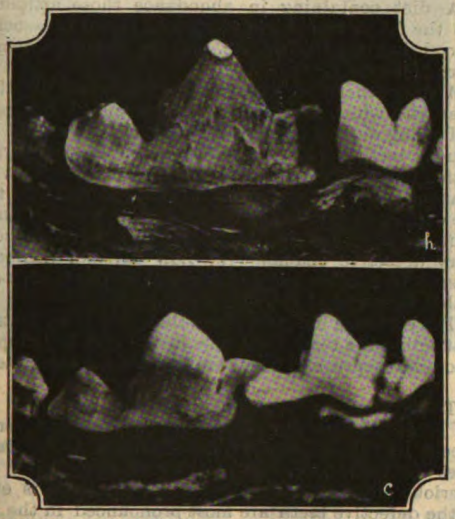
If we consider next one aspect of the chemical side of the problem, we see (Table II.) that the calcium content of the teeth may be influenced by the diet, although the actual intake of calcium salts would appear to be adequate.

TABLE II.

No. of exp.	Special factor in diet.	Tooth taken.	Wt. of dry tooth.	Total CaO.	% CaO.
90	Suet.	Lower carn.	1·451 g.	0·507 g.	36·4
90	,,	3 l. incisors.	0·438 ,,	0·156 ,,	36·1
94	Yeast.	Lower carn.	0·851 ,,	0·296 ,,	34·8
101	Butter.	,,	1·291 ,,	0·440 ,,	34·0
122	Calcium phosp.	,,	0·601 ,,	0·186 ,,	30·9
122	,,	3 l. incisors.	0·188 ,,	0·059 ,,	31·3
143	Linseed oil.	Lower carn.	0·851 ,,	0·260 ,,	30·5

It will be seen from the above table that there is a great variation both in the weight of the teeth and in the calcium content (reckoned as calcium oxide). For example, when either suet or butter is added to the diet the carnassials weigh 1·451 g. and 1·291 g. respectively, the calcium content being 0·507 g. and 0·44 g. CaO, while when the fat is linseed oil the weight of the tooth is 0·851 g. and the calcium content reckoned as CaO is 0 260 g.

FIG. 3.



Enlarged photograph of the lower carnassial of (*c*) and (*h*) showing white enamel only on the apex of the teeth.

Causation of Low Calcium Content of Teeth.

It may be suggested that the low calcium content in this and in other similar experiments is due to a deficiency of calcium in the diet. We should certainly expect that the calcification of the teeth and bones would be imperfect if the calcium content of the diet of young animals were deficient or even on the border-line of the animals' needs. This explanation, however, does not seem to cover the experiments here described. For instance, comparing Experiments 90, 101, and 143 (Table II.), the calcium content of the diet was, practically speaking, identical, and yet the calcification of the teeth is good in the first two cases and poor in the last. Then, again, referring to the puppies (*a*)-(*f*), the amount of calcium given was the same in each case, and yet the condition of the teeth was very different, and I have no doubt but that the calcium content of the teeth will prove to be greater in (*a*) and (*b*) than in any of the others, and that it will be least in (*f*).

The only explanation on the calcium deficiency hypothesis is that the calcium salts are not equally absorbed into the blood stream owing to the action of the different fats. The following experiments would seem to negative this criticism.

In Experiment 122 (Fig. 4 (*k*) and Table II.) 5 g. of calcium phosphate were added daily to the diet, the fat of which was linseed oil. The experiment lasted about 12 weeks. The deciduous teeth were late in being shed and the permanent ones were late in erupting. The enamel on many of the teeth was either defective or absent. The calcium content of one lower carnassial was found to be only 0·186 g. (CaO), the weight of the tooth being 0·601 g.

There is always the possibility that the puppy was unable to make use of the calcium in this form. To exclude this experiments are now in progress in which the quantity of separated milk in the diet has been raised to 400 c.cm. and more daily. The teeth, in the case of one of these puppies which has been dieted for nearly three months, are poorly formed, and there is, so far, no evidence that the increased calcium in the diet, although given in a natural form, has improved matters.

There does not seem much doubt, then, that the puppies received an adequate supply of calcium in a form which ensured access to the blood. There is evidence, however, that the ameloblasts and other cells, which normally regulate the deposition of calcium in the developing teeth, are unable to perform this function successfully, owing to the lack of one or more factors in the blood stream which normally regulate this function. This factor cannot be either proteins, carbohydrates, fats, or salts, but is possibly something of the nature of an accessory food factor. Whether this accessory factor acts directly on the special cells or indirectly through some other tissues, such as the ductless glands, remains to be seen.

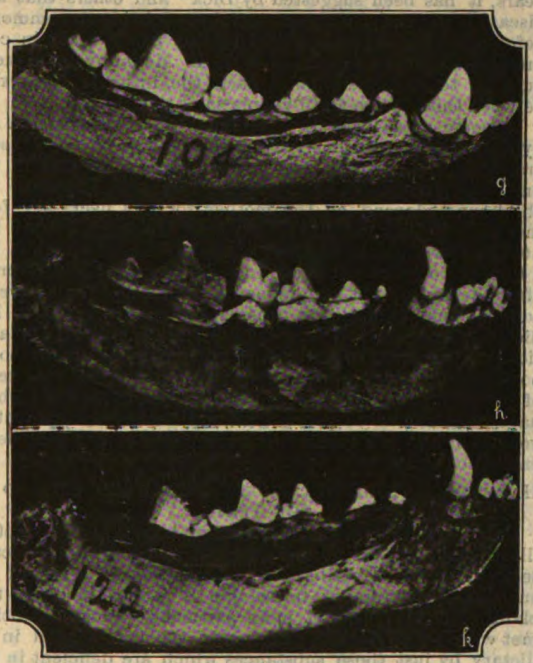
Effect of Time at which Diet is Started.

The appearance of the permanent teeth resulting from these deficient diets suggests that the extent to which the enamel, &c., is defective depends on the time at which the diet was started. In the human being the individual teeth calcify at different periods, starting before birth and ending at about 18 years of age. In puppies these changes cover a much shorter period of life; consequently one would not expect the picking out of specific teeth to be so prominent in puppies as it is in children. Nevertheless, even in puppies it is seen that in some teeth the enamel appears normal, while on others it is defective.

In the experiments so far completed the teeth most commonly affected are the lower carnassials. An examination of some of these teeth is very interesting. The enamel on the apex of the cusps may be white and shiny, while that on the rest of the tooth is either coloured (Fig. 3 (*a*)) or absent (Fig. 3 (*h*)). In Fig. 3 (*h*) the carnassial looks like a snow-capped mountain, for the only trace of white enamel is on the tip of the large cusps.

There is some evidence to show that, if the diet is only started when the puppy is over 3 months old, then the development of the teeth is little, if at all, affected. For instance, in Experiment 104 (Fig. 4 (*g*)), the puppy was

FIG. 4.



(*g*) About 7½ months old. 10 g. linseed oil per diem added to diet, which was, however, not started till the puppy was about 14 weeks old. The teeth appear quite normal. (*h*) About 5½ months old. 10 g. linseed oil per diem added to diet. Shows delayed dentition and imperfect development of enamel especially on the incisors and carnassials (see also Fig. 3 (*h*)). (*k*) About 5½ months old. 10 g. linseed oil and 5 g. $Ca_3(PO_4)_2$ per diem added to diet. Shows delayed dentition and imperfect development of enamel. (For CaO content see Table II.)

about 14 weeks old when the diet, containing linseed oil as the fat, was started. The teeth are white and shiny, and they are regularly arranged in the jaw. One lower carnassial weighed 1·412 g. and the CaO content was 0·501 g.

The Question of an Accessory Food Factor.

It is always possible that chewing hard crusts, bones, &c., may improve the circulation in the developing jaws and so cause better teeth formation, but it cannot explain the results described in this paper, for in no case was hard food of any kind given. From the point of view of bacterial

action and the production of toxic products, the diets would appear, in most cases, to be similar, except in so far as the fats are concerned.

What, then, is the factor (or factors) in the diet responsible for these changes? We have seen that the puppies fed on animal fats such as cod-liver oil, butter, and suet had the best teeth, whereas those fed on linseed oil had the worst. There is evidence that other vegetable oils—for instance, arachis oil and cotton-seed oil—also have deleterious effects.

As has been already suggested, the metabolic factors normally involved in the process of teeth development may be of the nature of accessory food factors. It is now recognised that fat-soluble A is present in abundance in cod-liver oil, butter, and animal fats generally, and is deficient in vegetable fats. The whole subject of accessory food factors and the part they play in health and disease is in its infancy, and therefore cannot be accepted as explaining in an unquestionable way facts such as are here described. But for the want of a better mode of expressing the general results of these experiments, one may say that a deficiency of fat-soluble A in the diet is accompanied by abnormal development of the teeth.

DEFECTIVE TEETH AND RICKETS IN CHILDREN.

A child's diet is most likely to be deficient in fat-soluble A from the ninth month to about the second year of its life; that is, at the transition period between a complete milk diet and one approximating to that of the adult. The permanent teeth calcifying at this period are the incisors, the canines, and the first molars, and it is just these teeth in children that are most commonly hypoplastic and carious. Since rickets is commonest in children during these early years, it has been suggested by Dick [2] and others that this disease is the cause of these special teeth being so commonly defective. The work described in this paper, taken in conjunction with the experiments of E. Mellanby on rickets, puts on to an experimental basis the intimate connexion between this disease and hypoplasia of the teeth.

In some cases even the deciduous teeth of children are hypoplastic and carious. Now the crowns of these teeth are developed, for the most part, before birth and in the first few months of extra-uterine life, and therefore the child must depend on the mother for any necessary food factors. McCollum [3] has shown that the animal body has not the power of synthesising these factors, although it has a limited power of storage. In order to supply her offspring after the first part of her pregnancy the mother must have an adequate supply of all the necessary accessory factors in her diet. If the accessory food factor theory is the real explanation of the facts described in this paper it ought to be possible to produce similar changes in the deciduous teeth of puppies by feeding a pregnant bitch on those diets which have been shown to prevent normal tooth development in young animals. Experiments on these lines are now being carried out.

HARMFUL NATURE OF MODERN DIETARY IN REGARD TO THE TEETH.

One can now see a rather obscure but still a real picture illustrating, in part at any rate, the cause of the defective teeth of modern civilisation. A perusal of a list of the substances containing fat-soluble A makes it clear that civilised conditions, and more particularly those conditions met with in urban life, exaggerate the part played in the dietary by just those substances which are deficient in this type of accessory factor. Our diet, particularly that of the poor, is now more than ever made up of specially prepared cereals, such as wheat, rice, oats, &c. Meat and the animal fats tend to play a smaller part. Vegetable fats, in the form of margarines, &c., are superseding butter, whole milk is being more and more excluded from the diet of the poor, partly at present because of the cost and partly because of a curious antipathy that many people have towards it. Then, again, with the development of civilisation, breast-feeding is not so commonly practised and, when practised, is often continued for only a short time. On the accessory food factor theory one can also understand why the Esquimaux in his own country, where flesh and blubber are the staple articles of diet, has such excellent teeth, while the inhabitants of Chili, who live chiefly on cereals, have teeth which are much less sound.

[2] Lawson Dick: Proc. R.S.M., vol. ix., p. 83.
[3] McCollum, Simmonds, and Pitts: Amer. Journ. Phys., vol. xli., p. 361.

There is no doubt that our modern dietary is harmful as far as the teeth are concerned, and, if the results of the present work and the deductions made are correct, the teeth of the people of this country will tend to become worse, unless our diet consists in the future more of whole milk and other foods containing fat-soluble A and less of bread, rice, potatoes, &c., which are deficient in this factor.

SUMMARY OF RESULTS.

1. A diet containing in abundance those articles with which the fat-soluble A accessory food factor is associated—e.g., cod-liver oil, butter, &c.—allows the development in puppies of sound teeth.

2. A diet otherwise adequate but deficient in the substances with which fat-soluble A is associated brings about the following defects in puppies' teeth: (*a*) Delayed loss of deciduous teeth. (*b*) Delayed eruption of the permanent dentition; in some cases the delay in the eruption of the permanent teeth is more marked than the delay in the loss of the deciduous teeth. (*c*) Irregularity in position and overlapping, especially of the incisors. (*d*) Partial absence of or very defective enamel. (*e*) Low calcium content; the deficiency in calcium salts may result in the teeth being so soft that they can be cut with a scalpel.

3. The evidence makes it clear that this is an instance of diet affecting the teeth from the inside and is independent of bacterial sepsis and other oral conditions associated with food.

4. These results cannot be considered as being due to acute illness or "malnutrition," for (*a*) the improvement to the teeth by the addition of fat-soluble A containing substances (animal fats, &c.) is as characteristic as the deleterious effect of a deficient diet; (*b*) there is evidence that the defective teeth are most pronounced in the rapidly growing puppies, and it is difficult to associate rapid growth with illness or "malnutrition," as generally understood.

5. This work, taken in conjunction with the experiments of E. Mellanby on rickets, puts the close relationship between hypoplastic teeth and rickets on to an experimental basis.

I wish to acknowledge with gratitude the advice kindly given me by Mr. Norman Bennett.

TREATMENT OF ANTE-NATAL AND POST-NATAL SYPHILIS.

BY JOHN ADAMS, F.R.C.S. ENG.,

MEDICAL OFFICER IN CHARGE OF THE THAVIES INN VENEREAL CENTRE FOR PREGNANT WOMEN.

IN THE LANCET of Nov. 23rd, p. 707, a report was published of a paper which I read recently before the Royal Society of Medicine. This paper was illustrated by a list of cases, reproduced now on pp. 772, 773, giving the results of treatment in regard to 24 babies born at the hospital of syphilitic mothers. Of these babies 5 were born with a negative Wassermann reaction; 7 became negative after treatment. Three mothers had no treatment before the death of the baby in utero. One baby died from syphilis; 1 died suddenly without any apparent cause; 1 was born dead. Six babies remain positive under treatment and are doing well. Six other babies were born of syphilitic mothers since the list of cases was drawn up, and of these 3 are already negative.

With the exception of 2 out of the 24 cases, the whole were cases of acute syphilis in the mother. They came in the primary or early secondary stage, and by taking cases of the babies at the beginning we were dealing with them at a time when the syphilitic virus probably has more effect on the child than it would have later on.

The first case has been under observation for six months. The mother has been treated, but not the child, and up to now nothing has developed.

There are no particular remarks as to Case 2.

Case 3 is rather interesting because it was a bad case of syphilis. I remember well Sir Jonathan Hutchinson, for whose memory I have the greatest regard, saying that the cases which were salivated very often did extremely well. In this case the salivation was severe.

In Case 4 the positive reaction in the child has remained, and the curious thing is that for nine months the child continuously gained weight, and, indeed, if I were choosing children for a baby show, this would be one of my selections.

CASE 7.

Case 5 went on the even tenor of its way, and the reaction remained negative.

In Case 6 the child went from strongly positive to positive, and put on 10 lb. weight; it would no doubt have become perfectly negative had the treatment been more regular. The treatment was interrupted in this case by an outbreak of eczema.

Of Case 7 a photograph is reproduced.

In Case 8 there is now only a suspicion of syphilis in the child. It was in the hospital about two months, and consequently there was a very short time in which to carry out complete treatment.

Case 9 became perfectly negative; this was one of the very bad cases at the beginning.

Case 10 also became perfectly negative.

Case 11 is another very interesting case. The child lost weight at one period of its career, but that was due to insufficient feeding by the mother. These mothers are often incapable of feeding the children by the breast only.

Case 12 was born negative, and on this case there is very little to say except that the mother had not recent syphilis.

Case 13 was also born negative.

Case 14 (see photograph) like Case 4, had a strongly positive reaction the whole time, except on one occasion when it was positive, but not strongly positive. In this case also the treatment was irregular, but it has been more regular recently, and now, since the list of cases was drawn up, it is only positive, not strongly positive.

CASE 14.

In Case 15 the child, I believe, died from syphilis. Only two injections were given. The child was very poor from birth and seemed extremely unlikely to live.

I pass over some of the ensuing cases, remarking that of these born dead some were probably dead before there was any treatment at all. A photograph is reproduced of Case 17.

Case 22 was an extraordinary case. This child was a 6½ months child as far as could be estimated and weighed only 3 lb. 4 oz. at birth. It had every sign of syphilis and seemed unlikely to survive more than a few days. It did not die, however, and its weight went up to 5 lb. 14 oz. Then, without any reason so far as could be seen it died quite suddenly in a screaming fit. I got particulars of the post-mortem, and so far as can be judged, there was no reason why the child should have died from syphilis.

Case 23 became negative under treatment. Case 24 was born dead, and probably had died before treatment was given at all.

CASE 17.

The progress of the babies is further shown in the following table:—

Weights at Weekly Periods after Birth.

Case 1.			*Case 4 (cont.)*			*Case 9 (cont.)*			*Case 14 (cont.)*

8	14	4.2.18	8	10	13.5.18	13	2	21.7.18	12	4	13.10.18

I am aware that the period of one year is all too short in which to bring these tests of syphilitic cases to perfection. I have given the subject, however, much thought and consideration, and I feel amply rewarded by the results.

TREATMENT OF ANTE-NATAL AND POST-NATAL SYPHILIS: DETAILS OF 24 CASES.

G.c., General condition. Pap. syphl., Papular syphilides. Nov., novarsenobillon. Salv., salvarsan; figure indicates number of injections. Iv. and Im., Intravenous and intramuscular injections respectively.
Explanation of Wassermann (W.) signs; Strongly positive, ++ (diagnostic). Positive, + (diagnostic). Feebly positive, ±. Negative, −.

AN INVESTIGATION OF THE

ANTISCORBUTIC VALUE OF THE RAW JUICES OF ROOT VEGETABLES,

WITH A VIEW TO THEIR ADOPTION AS AN ADJUNCT TO THE DIETARY OF INFANTS.*

BY HARRIETTE CHICK AND MABEL RHODES.

(*From the Lister Institute, Director's Department.*)

Low Antiscorbutic Value of Fresh Milk.

IN the study of the distribution among foodstuffs of the antiscorbutic accessory factor made recently by a group of workers in this Institute, a considerable amount of attention has been devoted to the antiscurvy value of cow's milk. A preliminary report of these experiments was published several months ago in THE LANCET, and the results[1] [2] have shown that cow's milk, even when fresh, is a substance poor in antiscurvy properties, and that a large daily ration, amounting practically to a complete milk diet, is necessary if scurvy is to be prevented by its agency alone.

This conclusion is in accord with the opinion previously expressed by certain clinicians on the basis of their observation of infant nutrition. Thus Barlow[3] in 1894 wrote the following words: "Looked at as antiscorbutic, probably much larger quantities of fresh uncooked meat and fresh milk are needed than fresh vegetables and fresh fruit juices." And at a later date Still[4] wrote: "The antiscorbutic power of fresh, unboiled milk is evidently slight."

In the case of young guinea-pigs it was found (*loc. cit.*) that a daily ration of 100–130 c.cm. of raw cow's milk was necessary to prevent occurrence of scurvy, and evidence was adduced to show that if the milk had been previously heated or dried a ration equivalent to the above would prove insufficient. These results have recently been confirmed by Miss R. E. Pilgrim, also working in this department, who has kindly permitted us to refer in this place to her experiments which will shortly be published elsewhere. It has been found extremely difficult to carry out the experiments with guinea-pigs. A full-cream milk diet is tolerated with difficulty by these animals, apparently owing to the high fat-content, and separated milk has proved easier of digestion. It has been exceptional to find young guinea-pigs which can consume as much as 100 to 150 c.cm. raw milk daily without digestive disturbances, even when the constipation occurring is mitigated by a daily dose of liquid paraffin. In the rare cases where this has been achieved good health and growth have been maintained for the period of the experiment—three months—and signs of scurvy have been absent or very slight. Upon a similar ration of dried milk this result has not been attained, even when the preparation is not more than 2–3 weeks old. Milk in this form is much better digested, and it is not unusual to find the equivalent of 100–130 c.cm. fresh milk consumed daily without difficulty. But in such cases the animals have suffered from severe scurvy sooner or later, and although life was prolonged the animals lost weight and sank into a miserable condition of chronic scurvy. There is little doubt that dried milk, even when freshly prepared, is inferior to raw fresh milk in respect of antiscorbutic properties.

Question of Extra Antiscorbutic for Infants.

In case of artificially fed infants the use of raw cow's milk is exceedingly rare at the present day. Boiling or pasteurisation of the milk has become necessary to obviate danger from bacterial disease, and for the same reason, as well as on grounds of convenience, the use of dried milk has increased largely in recent times. There is no doubt, however, that infants nourished upon boiled or dried cow's milk receive a smaller allowance of antiscorbutic material than would be provided by a diet of raw milk, and that the amount they obtain may dangerously approach the minimum required. To what extent this is a serious menace must depend upon the degree to which the content of antiscurvy vitamine in raw cow's milk is in excess of the infant's requirements and upon the antiscurvy value originally possessed by the particular sample of milk employed.

In any case the results of the experimental work are strongly in support of those medical authorities who recommend the inclusion of some extra antiscorbutic in the diet of infants nourished upon milk of which the original antiscorbutic value has been diminished by heating or drying.

Expert medical opinion is, however, divided upon this point. Many authorities, impressed with the comparative rarity of pronounced scurvy among infants brought up on boiled or dried milk, consider that the addition to that diet of any extra antiscorbutic is an unnecessary measure (see Coutts, 1918),[5] (Naish, 1914).[6] Others consider that the danger of incipient scurvy among artificially fed infants is not as negligible as is supposed (e.g., Hess and Fish, 1914)[7] (Miller, 1917),[8] and recommend that raw fruit juice or other antiscorbutic material should be added to the diet. Special attention was called to this point in an editorial article in THE LANCET of Sept. 22nd, 1917, and it is for the benefit of those who find difficulty, on account of cost or scarcity, in providing infants with an extra antiscorbutic in the form of fresh fruit juice that the following experiments as to other available sources were undertaken.

Experimental Work.

The experiments were made with young guinea-pigs, and the methods employed were the same as those described in the previous paper dealing with the antiscorbutic value of fruit juice in THE LANCET of Nov. 30th. The juices were prepared by rubbing the clean-cut surface of the raw vegetable upon an ordinary kitchen grater, placing the pulp in muslin and squeezing gently between the fingers, when the juice runs out readily. Unless otherwise stated, the juice was always prepared fresh every day; expressed raw vegetable juices undergo changes rapidly at room temperature, and were found to deteriorate in respect of antiscorbutic value when stored even at a low temperature in a refrigerator. In the accompanying table are set forth the results obtained

Table showing Antiscorbutic Value of Raw Vegetable and Fruit Juices.

Experiments with guinea-pigs. The diet consisted of oats and wheaten bran *ad libitum*, with 60 c.cm. daily of milk autoclaved at 120° C. for 1 hour; the antiscorbutic element in the diet was provided solely by the measured daily ration of vegetable or fruit juice.

Experiment No.	No. of animals.	Antiscorbutic material employed.	Daily ration.	Duration of experiment (days).	Result.	Degree of protection from scurvy.

with the raw juices of swede, carrot, and beetroot, the immediate aim of the experiments being to determine the minimum amount which, when added to a diet of oats, bran, and autoclaved milk (heated to 120° C. for one hour to reduce its antiscorbutic value to a minimum), was adequate to prevent scurvy and to maintain the animal in health over the

* A companion paper entitled The Relative Content of Antiscorbutic Principle in Limes and Lemons, together with Some New Facts and Some Old Observations Concerning the Value of "Lime Juice" in the Prevention of Scurvy, (A) *Experimental Inquiry*, by Harriette Chick, B. Margaret Hume, and Ruth F. Skelton, (B) *Historical Inquiry*, by Alice Henderson Smith, appeared in THE LANCET of Nov. 30th, 1918, p. 735.

period of the experiment. Results obtained with cooked potato (it is not possible to feed guinea-pigs on raw potatoes), fresh orange juice, fresh grapes, and fresh raw cabbage leaves, are added for purposes of comparison.

Comparative Antiscorbutic Value of Various Raw Vegetable Juices.

The juice of the fresh raw swede easily takes the first place in respect of antiscorbutic value. Protection from scurvy was attained with a daily ration of 2·5 c.cm. In case of raw carrot juice, severe scurvy developed in animals receiving daily rations of 5 c.cm. and 10 c.cm.; with a daily ration of 20 c.cm., protection from scurvy was secured and the general condition of the animals was about the same as of those receiving a daily ration of 2·5 c.cm. swede juice. In case of beetroot, the antiscorbutic value was less than that of carrot; animals receiving a daily ration of 20 c.cm. fresh raw juice showed only a small degree of protection, acute symptoms of scurvy supervened in every case, and death from scurvy occurred in several instances before the period of experiment, three months, had expired.

It is thus seen that raw swede juice provides a valuable and inexpensive source of antiscorbutic material. Its value is not markedly inferior to that of fresh orange juice, and it may be regarded as a satisfactory substitute; its value is 10 times that of raw carrot, and more than 10 times that of raw beetroot juice. It has recently been adopted in some infant welfare centres, and there does not appear to be any drawback to its use for the purpose of infant feeding.

Raw carrot has long been popular as an adjunct to the dietary of infants and there is traditional support for its worth. So keen an observer of his own day as Anthony Trollope, in "Barchester Towers," 1857, depicts the older generation in the person of Miss Thorne strongly advising the young mother to smear raw carrot juice and allow it to dry upon the baby's coral, in order to ensure for the infant a healthy set of permanent teeth in the future. "The receipt had been much in vogue in the young days of her (Miss Thorne's) grandmother," who "had the best teeth in the county and carried them to the grave with her at eighty." (Bohn's Library Ed., Bell and Sons, 1913, p. 234.)

It is interesting to observe the root vegetables investigated are widely separated in the vegetable kingdom; the swede belongs to the natural order *Cruciferæ*, the carrot to the *Umbelliferæ*, the beetroot to the *Chenopodiaceæ*, and the potato to the *Solanaceæ*. It is significant that the natural order *Cruciferæ* should also include the cabbage, most potently antiscorbutic of the vegetables investigated in the present inquiry, and the "scurvy grass" (*Cochlearia officinalis*) and the "cresses," so justly esteemed by the sailors suffering from scurvy in the old days.

Bachstrom (Observationes circa Scorbutum, 1734) relates the following remarkable story: "A sailor in the Greenland ships was so over-run and disabled with the scurvy, that his companions put him into a boat, and sent him on shore; leaving him there to perish, without the least expectation of a recovery. The poor wretch had quite lost the use of his limbs; he could only crawl about on the ground. This he found covered with a plant, which he, continually grasing, like a beast of the field, plucked up with his teeth. In a short time he was by this means perfectly recovered; and, upon his returning home, it was found to be the herb of scurvygrass." (Rendering given by Lind, 1757. A Treatise on the Scurvy, 2nd edit.). It is interesting to find that the old legend that the cruciform arrangement of the flower was an indication of especial virtues in the service of man thus receives scientific support at this comparatively late date.

Summary.

1. Cow's milk possesses distinct antiscurvy properties, but these are present in small degree in comparison with other antiscorbutic foodstuffs. Its value in this respect is further reduced after heating or drying. It is therefore advisable to provide some extra antiscorbutic material in the diet of infants nourished upon heated or dried cow's milk.

2. The antiscorbutic value of various materials that might suitably be included in an infant's diet has been experimentally determined by means of experiments with guinea-pigs. Among fresh fruit juices that of the orange is easily the most suitable, and possesses a value about ten times as great as that of fresh grapes. Of the raw vegetable juices examined, raw swede juice proved to be far the most potent, approximating in value to raw orange juice; the raw juice of carrots was found to be much inferior, and that of beet-roots failed to prevent scurvy in the largest dose (20 c.cm. daily) that could be administered to the experimental animals.

HÆMORRHAGIC BRONCHITIS:

CASTELLANI'S BRONCHO-PULMONARY SPIROCHÆTOSIS.

BY H. VIOLLE.

(*From the Institut Pasteur, Paris.*)

IN view of the fact that cases of broncho-spirochætosis (Castellani's bronchitis) have recently been observed in Europe—I have first found the disease in France, having recorded a large number of cases of it in Toulon—a few notes on the subject will perhaps be found to be of some practical interest.

This affection and its etiological agent were first described by Castellani in Ceylon in 1905.[1] He called the malady broncho-spirochætosis and the germ *Spirochæta bronchialis*. Castellani's observations were confirmed in various parts of the tropics, by Branch in the West Indies in 1907, by Jackson in the Philippine Islands in 1908, by Waters in 1908, who recorded a number of cases in India, by Phalen, Kilborne and Chamberlain, Taylor, Chalmers and O'Farrell, Harper, and others in various other tropical countries.

In Europe a few cases were observed in 1915 by Galli Valerio in Switzerland, one case by Lurie in Serbia, and a few by Castellani himself in the Balearic-Adriatic zone. Very little attention, however, was paid in Europe to the disease until it was found in France by myself in 1916. At Toulon, where I have been carrying out the investigation, a comparatively large number of cases has occurred among the native troops coming from the Far East, as well as in Europeans who had never been to the colonies. A special ward in the St. Mandrier Hospital had to be set aside for cases of this disease, and I was placed in charge of it.

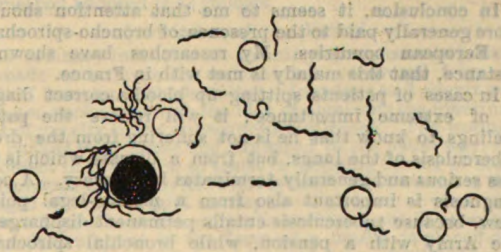
Symptomatology.—Mode of Infection.

The symptomatology I have observed in my patients is the following:—

The patient has generally been sent to hospital with the diagnosis of tuberculosis or suspected tuberculosis, and one can easily understand why this diagnosis has been suggested, as in very numerous cases the patient is spitting up blood. The bloody expectoration is often of a peculiar vividly pink colour, somewhat different from what one usually sees in hæmoptysis of tubercular origin.

The cough is frequent, sometimes more severe during the night. The physical examination of the chest in some cases reveals very little or nothing; in other cases there are signs of simple bronchitis with or no emphysema; in others there are signs of consolidation.

The general condition of the patient is often fairly good, even very good, and very often there is no fever.



The blood at times shows a slight degree of anæmia, due to the repeated attacks of hæmoptysis. The number of leucocytes is normal, and so is generally the leucocytic formula. (See figure.)

The microscopic examination of the sputum reveals presence of *S. bronchialis* in enormous numbers; the preparations are teeming with it.

[1] THE LANCET, 1908, i., 1384.

To put in evidence these spirochætes one may use the ultra-microscopic for fresh preparations, or one may stain with Romanowsky and similar methods. The best method is the silver nitrate one of Fontana-Tribondeau.

The *S. bronchialis* Castellani is an organism extremely variable in length, shape, and number of spirals; length 4 to 30 microns, mostly 7–14. According to Fantham these medium forms are derived from the long ones by transverse division.

Certain individual spirochætes have very few spirals, two or three, others have a large number with spirals very close; numerous intermediate types can be found. The spirochæte has been carefully investigated from a morphological standpoint by Fantham. It has not yet been cultivated. I have not been able to reproduce the disease in rabbits, guinea-pigs, and pigeons, but Chalmers and O'Farrell have reproduced the disease in a monkey by intratracheal injection.

The disease, according to certain authorities, is very contagious, the contagion taking place, according to Fantham, from infected persons to healthy individuals by means of the so-called "coccoid bodies" derived from the spirochætes. Without denying this mode of contagion, I am inclined to believe that *S. bronchialis* may be present in very small numbers in many individuals, similar to what is the case, for instance, with the pneumococcus, and that any cause lowering the vitality of the tissues, such as a chill, may cause *S. bronchialis* to multiply and to invade the whole of the broncho-pulmonary system.

As regards the possibility of spirochætic infections spreading from the mouth to the bronchi, I must say that, except in one single case, none of my patients had any mouth lesions of spirochætic origin, and their teeth and gums were in good condition.

Diagnosis and Treatment.

Diagnosis.—This is based on finding *S. bronchialis* in large numbers in the expectoration, while there is absence of the tubercle bacillus, of hyphomycetes, and of ova of *Paragonimus westermanii*, Kerbert, which at times may give rise to bloody expectoration. Clinically, if a patient presents bloody expectoration of a vivid pink colour and is in good health, the practitioner should be on the look-out for Castellani's broncho-spirochætosis. Cases of mixed infection of broncho-spirochætosis and tuberculosis occasionally occur; similarly, cases of bronchial spirochætosis plus broncho-moniliasis have been recorded.

Prognosis.—The prognosis, as a rule, is favourable; in many cases all the symptoms disappear within three to four weeks from onset. Relapses, however, seem to be frequent, and chronic forms occur with expectoration, which is at times muco-purulent, greenish, and at times mixed with blood.

Treatment.—In a large number of cases active therapeutic measures are not called for, rest, nourishing diet, and country air being sufficient to bring about a cure. Ergotine and tr. iod., a few drops well diluted, should be given if the attacks of hæmoptysis are severe, and if there is not much secretion and the cough is very painful opium preparations may be administered.

As regards specific treatment arsenic and tartar emetic have been used by Castellani and others, while certain authorities recommend arsenobenzol. Satisfactory results from such a line of treatment will at times be obtained in chronic cases.

In conclusion, it seems to me that attention should be more generally paid to the presence of broncho-spirochætosis in European countries. My researches have shown, for instance, that this malady is met with in France.

In cases of patients spitting up blood a correct diagnosis is of extreme importance; it will relieve the patient's feelings to know that he is not suffering from the dreaded tuberculosis of the lungs, but from a disease which is much less serious and generally terminates in recovery. A correct diagnosis is important also from a medico-legal point of view, because tuberculosis entails permanent discharge from the Army with a pension, while bronchial spirochætosis merely means in most cases giving the patient a few weeks' rest, after which he will be able to resume his military duties.

AT the instance of the National Council of Trained Nurses, Mrs. Bedford Fenwick will stand for election to Parliament on the National Health ticket when a suitable constituency can be found.

LOCAL ANÆSTHESIA AND TWILIGHT SLEEP IN THE SURGERY OF EXOPHTHALMIC GOITRE.

BY S. H. ROUQUETTE, M.CH. CAMB., F.R.C.S. ENG.,
RESIDENT ASSISTANT SURGEON, ST. THOMAS'S HOSPITAL.

DURING recent years an ever-increasing number of the subjects of Graves's disease have been submitted to operation with a measure of success which would have seemed scarcely credible in days gone by before the factors of safety were as well understood as they are now. That surgery can produce an immediate cure in some cases and marked improvement in others there can be no doubt, but time alone can show whether the cure is permanent.

Limitations of General Anæsthesia.

It is generally recognised that the only surgical measure likely to prove of permanent value consists in ablation of the greater part of the gland, the exact amount depending on the age of the patient, the severity of the disease, and on various other factors. As the determination of this amount is exceedingly difficult there are many cases in which a second operation is required still further to reduce the size of the gland, but with the growth of experience secondary operations are likely to become less frequent in the future.

The very great diminution in the mortality of the operation is due partly to a better appreciation of the time at which operation should be undertaken, but far more to a realisation of the danger of anæsthetics, culminating in the absolute prohibition of chloroform. Ether is still used, and in highly skilled hands is a safe anæsthetic for very slight or early cases, as well as for those which, though originally severe, have been markedly improved by a previous operation; but I am inclined to think it is not sufficiently safe for a primary operation in a severe case.

Of the various methods of administration the rectal is achieving popularity, and has found a warm advocate in Mr. A. J. Walton and others who speak with authority. I have not made an extensive trial of this method, but such experience as I have had has only served to strengthen my preference for local anæsthesia. On several occasions Dr. Z. Mennell has given ether for me by the intratracheal method with great success, but while I regard this as the most suitable for large, simple goitres with respiratory embarrassment, it is limited by the conditions formulated above.

Local Anæsthesia.

Foremost among pioneers in this branch of surgery, Dr. T. P. Dunhill, of Melbourne, will ever be remembered as the champion of local anæsthesia; readers of THE LANCET are familiar with his teaching and aware of the results he has obtained. No one who read his paper of Dec. 15th, 1917, can fail to have been impressed by the extraordinary recovery of the most desperate cases under his care, cases which could only have terminated fatally in a very short time but for his intervention. Dr. Dunhill himself attributes his successes to the use of local anæsthesia, and, indeed, if one may judge from the photographs in his paper, it would seem doubtful whether any anæsthetist could have been found willing to deal with patients in so grave a condition.

Surgeons in this country have tried local anæsthesia, but do not seem addicted to its use. It certainly possesses two disadvantages: in the first place, the mind suffers what the body does not feel; and, in the second, the personality of the patient is apt to intrude and embarrass the surgeon, with the result that the operation may degenerate into a trying ordeal for both. In such circumstances the surgeon is hindered in his work and may be unable to remove an adequate proportion of the gland. Local anæsthesia cannot abolish the pain arising from certain of the manipulations; but while some patients bravely resign themselves and tolerate discomfort without flinching, others are physically incapable of exercising the necessary self-control. When it is remembered that the patients are sufferers from Graves's disease, it will be realised that local anæsthesia must often leave much to be desired.

It was with a view to improving the technique and alleviating the distress of the patient during the operation that I began to use preliminary injections of morphine and later of hyoscine as well. I found that the operation could

be more quickly performed and that the patient frequently felt nothing at all or slept peacefully at intervals throughout the operation. The drugs produced no ill-effects and sometimes enabled the patient to sleep for the remainder of the day.

Technique.

1. *Induction of amnesia.*—For each individual it is necessary to estimate what dose of the drugs will be required and how long it will take to produce the desired effect. Most frequently I give hyoscine 1/100 gr. and morphine 1/6 gr. an hour and a half before the operation and morphine 1/4 gr. half an hour later. The patients' ears are plugged with wool and the room is darkened at the time of the first injection.

2. *Syringe and needles.*—I use a 20 c.cm. Record syringe, with Barker's steel spinal needles and hypodermic needles.

3. *The anæsthetic solution.*—Dr. Dunhill uses 200 c.cm. of saline containing 0·1 per cent. adrenalin 20 m and novocaine 6 gr. Hoffmann and Kochmann [1] recommend—

Novocaine	0·2 g.
Sol. pot. sulph. (2 per cent.)	40 g.
Sol. sod. chlor. (0·9 per cent.) ... ... ad	200 g.
Sol. suprarenin hydrochlor. (0·1 per cent.) ...	24 m.

The addition of potassium sulphate to a novocaine solution is said to aid its effect, and magnesium sulphate is sometimes used with a similar object. Whatever solution is employed should be freshly prepared, but need not be warmed before use. Of the two chief ingredients the adrenalin is the more important; it diminishes oozing from the subcutaneous tissues and prevents too rapid absorption of the fluid. I doubt whether the novocaine is really of any value at all at so low a concentration, as I have been equally successful with normal saline alone except for a slight increase in capillary hæmorrhage. I think the anæsthesia is produced principally by distension of the tissues, since the large volume of the fluid seems to be the most important factor.

4. *The injection.*—The injection can be made through one median puncture, and as the introduction of a large spinal needle is painful, it is well to begin by infiltrating the puncture area with a fine hypodermic needle. With very nervous patients I sometimes introduce a further refinement by laying a pad soaked in 1 : 20 carbolic on the neck beforehand to diminish sensibility to the prick of the needle. All the tissues superficial and lateral to the gland can be infiltrated, but the fluid does not penetrate the capsule of the gland and seldom reaches the trachea; posteriorly the structures never show any evidence of infiltration. The injection is begun half an hour before the operation while the patient is still in bed; he is then conveyed to the operation theatre, and by this time is usually drowsy and takes no interest in subsequent proceedings. It is not necessary to inject any more of the novocaine solution during the course of the operation.

5. *The operation.*—During the operation the theatre is kept as quiet as possible and no talking is allowed; the patient may sleep the whole time, moan subconsciously, or rouse himself at intervals to ask questions. Occasionally the limbs move slightly, but whatever impressions the brain may receive the mind retains no recollection of them. The loss of all idea of time is a noticeable feature, and when asked how long he supposed the operation took the patient will usually under-estimate the time by half an hour or more; he does not afterwards feel that he has passed through any painful ordeal, and in most cases the pulse does not rise appreciably during the operation. I have not always succeeded in producing complete immunity from discomfort, but with increased experience imperfect anæsthesia has become exceptional.

6. *Post-operative course.*—I always drain the wound and close the incision with clips; the drainage-tubes and some of the clips are removed two days after the operation and, if the wound then shows no tendency to gape, the remaining clips are removed on the following day. In the majority of cases the post-operative course is extraordinarily free from discomfort of any sort, the patient altogether escaping the physical and mental distress so apt to follow in the wake of general anæsthesia. The narcotics produce no ill-effects unless given in excessive doses when headache and thirst may be complained of; headaches are readily alleviated by aspirin and thirst by administration of fluids in any form most palatable to the patient.

[1] Deutsch. med. Woch., 1912, No. 48.

The temperature is always raised for a few days, but usually rises no higher than 101° F.; in some cases and for no apparent reason it remains irregular for two or three weeks, and then slowly falls to normal, provided that absolute rest is enforced. The pulse reaches its highest point on the second day, and thereafter falls steadily during the next ten days to a level below that recorded before the operation. I have not found that local anæsthesia increases the likelihood of suppuration, as the wound nearly always runs an aseptic course and heals by first intention, but the formation of a hæmatoma is not unlikely to occur if more than 0·1 per cent. adrenalin 20 m has been used in the anæsthetic solution. Occasionally alarming symptoms arise and call for prompt treatment. Great acceleration, and particularly irregularity, of the pulse indicate fatigue, when an effort should be made to induce repose of body and of mind; in these circumstances a dose of paraldehyde in rectal saline will often bring about a marked improvement. If, in addition, the patient is dyspnœic, cyanosed, and restless the condition is more serious; the wound should first be examined to make sure that drainage is not obstructed, and then strophanthin should be injected intravenously; for this purpose I keep in readiness a freshly prepared solution containing strophanthin gr. 1/250 and adrenalin (0·1 per cent.) 1 m, in 5 m, the effect of which is instantaneous. Inhalation of oxygen is sometimes useful in relieving cyanosis.

Soreness of the throat and difficulty in swallowing are minor complaints and are sometimes distressing; they can be relieved by the use of suitable lozenges and by giving small pieces of ice to suck. Vomiting hardly ever occurs as a result of the operation and is never serious by itself, though attacks of vomiting may have been one of the manifestations of the disease. The presence or absence of various complications depends largely on the severity of the disease and on the area of the cut surface of the gland from which secretions may be absorbed into the circulation.

Conclusions.

The combination of hyoscine-morphine amnesia and local infiltration is an absolutely safe method of producing anæsthesia, possessing neither disadvantages nor contra-indications; it is preferable to local anæsthesia alone, and more rational.

THE TREATMENT OF EXTENSIVE SEPTIC WOUNDS.

BY H. GARDINER, M.S. LOND., F.R.C.S. ENG.,

ACTING ASSISTANT SURGEON, ROYAL FREE HOSPITAL AND EVELINA HOSPITAL FOR CHILDREN; OPERATING SURGEON, FULHAM MILITARY HOSPITAL; SURGICAL REGISTRAR, CHARING CROSS HOSPITAL.

IT seems that the chief use of gauze dressing is that it protects the wound from secondary infection from outside, and that if a method of treating wounds can be devised in which the wound is protected from outside infection, and at the same time the objectionable results of the use of gauze dressings are eliminated or diminished, an advance in the right direction will have been made. With this object I have, for the last six months, been treating septic wounds with much discharge with no permanently applied dressing. The method adopted is as follows.

Description of the Method.

The ordinary incisions for opening up recesses in pockets are made as soon as the patient has recovered from the result of transfer to the hospital. Incisions and openings so made are performed with the idea of obtaining the maximum effect of gravity in the subsequent treatment. The wound is then packed with gauze and bandaged in the usual way—the sole object in this being to assist in stopping oozing of blood. All dressings are removed 48 hours later. The wound is then syringed with some mild antiseptic—e.g., boric or weak eusol lotion. A guard made from perforated zinc, cut in an appropriate size and bent in the form of a cradle, is placed over the limb or part wounded and covered by a sterilised towel. If possible, an ordinary cradle is placed over the whole. Any discharge from the wound is allowed to run out from the wound, and is taken up by a sterile pad of wool or sphagnum moss so placed as not to touch the wound. At intervals varying with the amount of discharge, on an average twice a day, or in some cases more frequently, the nurse lifts the towel and zinc guard, syringes or swabs the wound, and changes the pad. The guard and towel are then replaced. This treatment is continued until all pockets and recesses have been closed by granulation, the granulating surface is

smooth, and the discharge has practically ceased. The wound is then dressed in the ordinary way with gauze and wool.

A fair number of cases (40 or 50) have been treated in this way, and in none of them have any bad effects been observed as the result of leaving the wounds open. In some of these the wounds were so extensive, and the discharge so foul and profuse, that amputation on admission was seriously considered. Wounds infected with a great variety of organisms —all those commonly met with in such wounds—have been treated in this way with success.

Occasionally it has been necessary to open pockets that have formed after the treatment has been started, but these were all cases in which it had been impossible to obtain a proper flow of discharge by gravity. In these cases a small wick of gauze is laid wherever a recess is found and left hanging over the edge of the wound to assist in the drainage. These wicks are never so large as to occupy more than a quarter of the opening of any recess.

Its Difficulties and Advantages.

The difficulties experienced in this method of treatment have been threefold: 1. Difficulty in some cases in arranging the wound by operation for opening pockets or by altering the position of the patient so as to obtain the greatest effect of gravity. This difficulty is to some extent overcome by the judicious use of very small gauze wicks and by the more frequent cleansing of the wound by syringing. 2. The difficulty in continuing the treatment at night when the patient is asleep and restless, as any considerable movement of the wounded part may disturb the covering and bring the wound in contact with unsterilised material. This is overcome in some cases by placing the limb in a splint. In others it is necessary to place an ordinary dressing and bandage on at night, but the number of cases in which this has had to be done is small. 3. Some parts of the body are difficult to keep covered in the manner described—e.g., the neck and side of the trunk—and in some parts—e.g., the face and head—it is impossible. In the case of the neck and side of the trunk it is possible to build up a rampart of sphagnum moss round the wound and to keep these in place with a towel or bandage in the usual way. The principles of perfectly free and open drainage is thus not interfered with.

The advantages following the employment of the method have been found to be: 1. Perfectly free drainage. 2. Absence of the tendency to pocket, provided the wound is exposed and so arranged as to allow gravity its maximum effect. 3. Absolute painlessness of dressing even the most extensive wounds—an advantage of prime importance for the general condition of the patients. 4. The dressings can be performed with a complete absence of any manipulation of the wounded part, as no bandages have to be removed or applied. 5. A great economy in dressings is effected.

With regard to the disadvantages mentioned above, the following comments are apposite: 1. All the advantages of the absorbent power of gauze in assisting drainage contrary to gravity can be obtained by the use of small wicks, with none of the disadvantages of the closed dressing. 2. Wounds (so severe as to need any special care in treatment) of "difficult parts," such as the head and neck, are only occasionally met with in general hospitals in England. A circular rampart of absorbent material, covered and kept in place by a sterile bandage or towel, has been effective in the small number of these cases that have come under my care.

The first effects of this method of treatment are somewhat disturbing to the mind of a surgeon accustomed only to the appearance of wounds treated in the ordinary way. The edges of the wound and parts of the surface over which the discharge is not flowing tend to become hardened and small scabs develop. These should be removed as soon as they have formed, and can usually be prevented from forming altogether by careful cleansing and swabbing of the wound. Should there be any recesses in the wound these must receive particular attention at the dressing, as there is a tendency for the discharge to coagulate and block up small fissures. Provided the dressing is done with ordinary care this can in all cases be prevented. In cases where deep pockets are present that cannot be effectively opened a rubber drainage-tube is employed to prevent premature closure. In cases where an ordinary closed dressing has to be applied at night a wet one is always used—usually a hot fomentation. Any tendency towards drying of the wound is thus prevented, even when it has been allowed temporarily to occur. The hypothetical objection that the dried secretion may block the recesses of the wound has not been proved to be valid by experience.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CÆSAREAN SECTION THREE TIMES ON THE SAME PATIENT.

BY WALTER G. SPENCER, M.S. LOND., F.R.C.S. ENG.,
SURGEON, WESTMINSTER HOSPITAL.

THE following case shows that Cæsarean section, sepsis being excluded, may be repeated without any impediment from scars or adhesions.

Notes of Case.

In April, 1907, the patient, then aged 29, in her first pregnancy, had reached term when labour pains began. A medical practitioner, recognising that natural delivery was impossible, sent her forthwith into hospital. On admission it was noted that she was a spare woman of medium height, who presented no external deformity. The pelvis resembled that of a boy. Measurements made subsequently, and repeated later, were as follows: True conjugate, 2¼ in.; transverse diameter, also outlet between ischial tuberosities, not much wider than conjugate; external conjugate, 7¾ in.; between anterior superior spines, 9 in.; between crests of ilia, 10¾ in. The uterus was high up; the cervix could scarcely be touched with the finger; the unruptured membranes were bulging through the os. No sepsis had been started. Cæsarean section was done within 24 hours of the first labour pain.

Mother with her three children after third Cæsarean section.

The second operation was performed in October, 1910, on what was reckoned to be the 280th day of pregnancy; labour had not commenced but the breasts had become full.

Cæsarean section for the third time was carried out in July, 1918, with the patient in the same state as at the second operation.

Account of Operations.

There was no essential difference between the three operations. The incision through the abdominal wall was a median one; at the second and third operations a fine strip of scar was excised, there was then no sign of hernial protrusion, nor of adhesion to the peritoneal aspect.

The incision into the uterus was also through the middle line, without encroaching upon the cervix or uppermost end of the fundus. At the second and third operations the abdominal wound was well retracted, but no one present could see any sign of scar in the uterine wall, or of adhesion to the uterus.

On opening the uterus the child, followed by the placenta and membranes, was removed with one sweep of the hand. At

the second and third operations the placenta was found attached, as at the first, above and behind, and it and the membranes peeled off just as readily. The cord was not tied off for two or three minutes, then the child was put to the breast as soon as it had been washed; it was afterwards suckled without any other food being given. All three babies throve without a break.

The uterus began to contract immediately it was squeezed; the contraction was just as quick on the second and third occasions, as at the first when labour had already commenced. After a long strip of gauze had been drawn down and out through the vagina, the uterine wound was sewn up by a double row of interrupted kangaroo-tendon sutures. When this had been completed the uterus had become quite hard, and no blood could be squeezed out between the sutures. Then the abdominal wall was as carefully sutured with three rows of interrupted kangaroo-tendon sutures and a continuous fine silk suture through the skin. By far the longer part of each operation was occupied by the insertion of the sutures.

As for the patient during and after the three operations, it was the same as if she had been operated upon for an uncomplicated ovarian cyst. The lochia and the involution of the uterus offered no differences from a normal labour.

The photograph shows the mother with her three daughters after recovery from the third Cæsarean section. She then had a perfectly sound abdominal scar.

Portland-place, W.

A CASE OF GUMMA OF THE ENTIRE LEFT LUNG.

BY ROBERT HALL, JUN., M.B., B.CH., B.A.O. BELF.,
CAPTAIN, R.A.F.; AND LATELY SURGEON PROBATIONER, R.N.V.R.

THE following case may be of interest on account of the rarity of the condition:—

Patient, aged 40; family history good, no malignancy, married, and has three children living. He states that they are healthy; a fourth child died of "convulsions" at the age of 10 months. He is, and was, a moderate drinker and smoker. He is a labourer in a flour-mill and attributed his present condition to an accident in July, 1914. Several bags of flour fell on him and he was away from work for a month; he felt breathless and easily tired upon slight exertion, and had a severe pain in his back, left shoulder, and left arm. He returned to light work, but frequently had to rest. His appetite became impaired and he had a cough. The dyspnœa gradually became more marked, and after several periods of alternate work and "lying up" he entered hospital in June, 1918, when his condition was as follows:—

Patient complained of constant pain in his left side, left shoulder and back, also shortness of breath and a cough with tough spit, which was very difficult to get up. (It was not blood-stained or prune-coloured.) Very little exertion exhausted him, and he had headaches. His appetite was poor, but he had not lost weight to any considerable extent during the past year.

Patient was emaciated and pale, and did not speak distinctly. His teeth were very bad, and there were "snail track" ulcers to the right of his uvula. The abdomen and bowels were normal. The heart was hypertrophied downwards to the sixth rib, and outwards to the left 2½ inches beyond the nipple line. The impulse was of a heaving type, and a diastolic murmur was heard in the aortic area with maximum intensity at Erb's point, and conducted to the apex. The electrocardiograph showed predominance of the left ventricle. The pulse was 108 and "Corrigan's"; the condition of the artery walls was fair. Epigastric and jugular pulsation was present. Blood pressure: Right arm, systolic 120, diastolic 76; left arm, systolic 106, diastolic 68 mm. Hg. Respirations were shallow and 40 per minute. The movement of the left side of chest was impaired. Vocal fremitus was absent over the entire left lung, "stony" dullness over whole left lung, and vocal resonance absent except over a small area extending from the sterno-clavicular junction to a distance of about 2½ inches in radius. In this area there was amphoric resonance. The nervous and genito-urinary systems were normal and pyrexia was not present.

The patient denies having had syphilis, but Wassermann reaction was markedly positive. He was put on anti-syphilitic treatment, and under large doses of potassium iodide his cough and breathlessness have been very much relieved. The possibility of actinomycosis was considered and ruled out.

In conclusion, I wish to express my thanks to my father, Dr. R. Hall, for permission to examine and take the history of this case.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Reconstruction in Medical Education and Practice.

AT the ordinary meeting of the society held on Dec. 2nd, under the presidency of Dr. ARTHUR F. VOELCKER,

Mr. H. J. WARING (Col. R.A.M.C.) introduced a discussion on Reconstruction in Medical Education and Practice. It was, he said, impossible to divorce medical education from medical practice. The objects to be aimed at in medical reconstruction could be put in the following brief form: (1) to improve the education of students so as to make them more efficient for medical practice; (2) to improve the conditions under which medical practice is carried on; (3) to obtain the largest output of good work from medical men with the least expenditure of energy; (4) so to arrange the conditions of medical practice that the practitioner could have more time for recreation and more opportunities for bringing his medical knowledge up to date. He was assuming that it was not the intention of the State to create a whole-time medical service; the draft Bill did not foreshadow that.

The Medical Curriculum.

Five years was too short a period of study if clinical subjects were to be adequately taught. When, in 1892, the medical curriculum was lengthened to five years it was the intention that the added year should be devoted to clinical work, but owing to some deficiencies in organisation and to some matters concerning the organisation of the schools the preliminary subjects still occupied the whole period. Two suggestions had been made to remedy that. The first was that the chemistry, physics, and biology course should be completed before the commencement of medical study; this could be done by rearranging the work at the public and secondary schools in the case of students who did not go to the older universities. In many public schools the courses of instruction were so arranged that the chemistry, physics, and biology taught sufficed for the first examination; the same was also true, to a lesser extent, of many secondary schools. If the need were made very clear the public schools would also fall into line. In Scandinavia the period of study had been extended to six years, and he was told by medical men there that it was satisfactory; but he thought the better solution of the difficulty was the completion of the chemistry, physics, and biology before entering the five-year course of medicine and surgery.

Medical Education.

He felt that anatomy should be taught by professed anatomists, but taught less from the morphological than from the surgical side. These professors should be shown the need for emphasising the latter aspect—i.e., in the use of the living model and the normal X ray appearances, especially in regard to the bones. It was also absolutely necessary to teach the lymphatic system of the body more thoroughly. There should be a schedule of anatomy, for some parts need not be taught in detail, such as learning every individual muscle of the back. Owing to the paucity of material, he thought it necessary that there should be a new Anatomy Act; and if that were the general view there should be a collective representation made, for the present was an opportune time. Applied anatomy would have a fitting place during the clinical period, and should be taught by a surgeon. Physiology had become such an enormous subject that its professors showed a tendency to teach it as a science apart, rather than human physiology as a factor in general medicine. The chemist should be attached to this department, and the time had now arrived for the general inclusion of a biochemist. Pharmacology should be taken in the intermediate period, in close association with physiology. He thought that the essentials of bacteriology should be taught before the student commenced his actual medical work; it could be done in a compulsory three months' elementary pathology and bacteriology course.

With regard to materia medica the student had an enormous amount to learn, as the Pharmacopœia was now very extensive. A number of physicians and surgeons could probably cut it down to one-half with advantage to the

medical student and without material disadvantage to medical practice. General medicine and surgery were well taught in all the medical schools. He had a suggestion to make, however, with regard to midwifery and gynæcology—namely, that separate teachers should be appointed for these two subjects. There had been a great tendency for the teaching of midwifery to be left to the younger man; when the teacher was older he inclined to the gynæcological or surgical side. There were now many special departments, and as medical education was at present constituted it was almost impossible for the ordinary student to go through all of them satisfactorily. The medical student should go through a special course in each one of these. Owing to the difficulties in providing material the majority of students never went through any satisfactory course in operative surgery; it was usually only those who went in for the higher degrees who did so. Concerning the equipment of the medical student for practice, he thought the teaching of mechano-therapeutics and massage was not satisfactory in any of the schools, yet many conditions could be only treated satisfactorily in that way. Consequently, that branch of practice went, by default, to quacks. In the States the gentleman who called himself an osteopath got a big practice. Mechano-massage should not be taught alone to the medical student; nurses should be included. He would have much more done in the teaching of preventive medicine; he did not mean public health work and sanitary science, but the prevention of the occurrence of disease. That was very much wanted in English medical schools. There should also be included in the curriculum a definite course on medical ethics. At present, to a great extent, the student had to learn it after he had entered on practice. It need not be an extensive course. Nurses should be regarded as part of the medical profession, but in the past they had not been catered for as they should have been. He did not think nurses were given sufficient opportunities for doing surgical dressing. It was also a question whether surgical sisters and those in charge of operation theatres should not have practical instruction in administering anæsthetics. In military practice during recent years they had done very useful work of this kind.

Post-graduate Study: Medical Schools: Conditions of Medical Practice.

With regard to post-graduate schools he thought that in London the profession had made a mistake. In most of the schools an attempt was made to teach graduates and undergraduates together. It would attract many to the wealth of clinical material in London if graduates could have courses distinct from those for undergraduates. At the present time most of the medical schools in London were associations of private individuals for the instruction of students, and their emoluments were derived from the fees paid by the students. He did not think university education could be satisfactorily carried out on the fees paid by the student. Recently the Board of Education had given grants to some schools, and those had during recent years enabled some of them to survive. He did not think the method of giving grants was a good solution. Every medical school should be a corporate body; should be controlled by a governing body, both professional and lay. The large hospitals should, he thought, have an arrangement by which the members of the Navy, Army, and Air Services could have definite study courses in the schools. It seemed a pity that as men became seniors in these services they were made administrators, to the loss of the scientific side.

He also made a plea for team work in ordinary practice; practices should not be a one-man concern, but should consist of men with varied qualifications, so as to ensure thorough investigation for every patient. London was worse provided than any other place with private institutions for medical and surgical treatment. Many of the "surgical homes" had been chosen because the property was cheap, and in some the sanitary and other arrangements were very unsatisfactory. Some were a definite disgrace to the profession. Under the new Ministry of Health he would have it as a condition that every one of these houses should be passed as in a fit sanitary condition before it was allowed to be so used. An interesting question was as to how far it was desirable for a nursing home to belong to a medical man. He thought such homes ought to be legitimately possible provided they were certified by some public body as suitable.

Much had recently been heard about making an A 1 community out of C 3 material. As things were at present constituted he did not think that was possible. The criminal, the congenital idiot, the feeble-minded, and such people were allowed to go free so long as they were not dangerous to the community. Two feeble-minded folk married, or did not marry, and additions to the C 3 ranks ensued. That could probably only be effectively stopped by means of sterilisation. Lastly, how far was the profession justified in prolonging the dreary lives of people suffering from incurable and crippling conditions, such as ectopic vesicæ and imperforate anus?

Discussion.

Sir JOHN BROADBENT dealt in detail with most of the points raised by the opener. He thought the teaching of biology was the difficulty in Mr. Waring's plan for the preliminary subjects. He agreed that the teaching of physiology could be overdone as a factor in medical study. If there was to be really good post-graduate teaching, such as would attract those from other countries, there must be professors or, at least, teachers who could devote a good deal of time to the work, and there should be a central place for such instruction. Cases could be lent to illustrate the teaching, and periodic visits to wards of hospitals could be arranged to see the bed cases. He agreed that the fees for teaching at medical schools were ludicrously inadequate, and it was impossible to run a school on the fees paid by the students. One of the great drawbacks of the London schools was the eternal competition, in which fees played a part, for many intending students carefully inquired as to where the fees were lowest. Much more coöperation between the various schools was needed. Perhaps under the Ministry of Health or of Education grants would be increased. He thought the present military hospitals could be converted into civilian nursing homes, but he did not think medical men should run them.

Dr. FORTESCUE FOX spoke of the want of greater recognition of mechano-therapeutics. Shortly before the outbreak of war a definite and strongly backed proposal was made to the Senate of the University of London to establish a chair in Hydrology; certainly it was a subject which should be systematically taught.

Mr. H. W. CARSON emphasised the need in London of properly organised post-graduate teaching. There were many institutions here, apart from the large teaching hospitals, which carried on a very good work, but in them it was very difficult to organise a scheme by which the material could be utilised. Many felt that after the post-war settlement England would be the great centre for post-graduate teaching in the Old World. The profession in this country ought to set to work to render it so; he was convinced it could be done. He agreed as to the need for more tuition to nurses, and that had been fostered in the institution with which he was connected. He did not think nurses should administer anæsthetics, because the responsibility in connexion with that, in the present state of the law, devolved on the operator. The medical work in the Army and Navy ought, in his opinion, to be remodelled. It was ridiculous that when a medical man in those services arrived at seniority he automatically ceased to do his special work. He agreed that team-work produced very good results if properly done.

Dr. SEYMOUR TAYLOR thought that at the end of the last century clinical medicine was very indifferently taught as a whole, though there were isolated and brilliant exceptions. North of the Tweed very much more use was made than here of every bit of clinical material. Some men in London, though they had not the faculty for imparting knowledge, held on to their posts for many years, their entry on such posts having probably been determined by distinction in mathematics or classics. Some of the schools he would not suppress but amalgamate.

Dr. C. O. HAWTHORNE thought the very atmosphere in a class on medical jurisprudence was an education in medical ethics without the need of a special class. He objected to the proposal to reduce the Pharmacopœia to half, as that book was created for the benefit of the public; its definitions had the force and authority of law. If London were to become, as it should be, the great centre for post-graduation teaching there must be a post-graduation hospital, and in connexion with that a college. On the

general question each hospital in the country should be made a centre to which medical men could feel, in a moral sense, they were at least attached, in the same way as all solicitors felt their attachment to the High Court.

Dr. E. KINGSCOTE spoke of the need for centralised work in the promotion of post-graduate teaching.

Mr. N. BISHOP HARMAN referred to the great mass of unused clinical material resident in the many Poor-law institutions. He also had a word in favour of the study of anatomy from the morphological standpoint. If the medical profession in this country had sufficient imagination they could bring about amazing developments along the lines which had been alluded to. He hoped the subject would be brought forward again.

Mr. G. Q. ROBERTS (secretary of St. Thomas's Hospital) alluded to the question of examinations, and thought some reform was needed. At present it seemed practically impossible to get medical students into the special departments; they felt they had not the time to spare owing to the need to pass their various examinations. It was extraordinary how ignorant many schoolmasters were as to how to prepare boys for their preliminary examinations. Mechano-therapeutics was a well-established department at his hospital, where 1250 treatments per week were being given. Men needed to "get their fingers on to" cases, not merely to sit in rows and listen to what was told them about the cases.

Professor J. G. ADAMI strongly supported the idea that efforts should be made to make England the great centre for clinical teaching. To do that the present time afforded a unique opportunity.

Mr. WARING replied.

SOCIÉTÉ DE BIOLOGIE, PARIS.

THE following is a summary of some of the papers read at meetings of this society held on Nov. 9th and 16th:—

C. LEVADITI. — Antistreptococcic Vaccination in Gunshot Wounds.

L. obtient un pourcentage global de succès; s'élevant à 92 per cent.; sous l'influence de ce traitement, combiné avec les autres procédés classiques pour les plaies de guerre, le streptocoque disparait, et on n'a plus affaire qu'à un traumatisme banal.

L. MOREAU.—X Ray Shadows at the Lung Hilus.

Les ombres hilaires observées sur le vivant ne se retrouvent pas sur le cadavre. Il semble donc que la théorie, d'après laquelle ces ombres seraient produites par le sang circulant dans les vaisseaux du hile, soit plus vraisemblable. Toutefois lorsque ces ombres ont une tonalité très élevée, les ganglions péribronchiques participent à leur formation.

ARTHUS and SIECHART.—The Dosage of Pepsine.

I° Préparer une liqueur gélatineuse acide. La répartir on deux séries de 10 tubes. Ajouter à chaque série respectivement, 0, 1, 2, 3, &c. gouttes de suc gastrique, et 0·1: 2, 3 &c., gouttes d'une solution type de pepsine dans l'eau. Laisser ces tubes pendant 24 heures à température du laboratoire. Les tubes sans pepsine sont gélifié. Noter la durée de l'écoulement de 5 cmc. du liquide de chaque tube, aspiré au préalable dans une pipettte. Comparer les nombres obtenus dans les 2 séries. Connaissant la quantité de pepsine de l'une des séries, on la calculera pour l'autre.

M. AYNAUD.—Malaria and Associated Infections.

Il est difficile d'apprécier le degré d'immunité des paludéens à l'égard de la grippe. Le paludisme ne crée pas un état d'hypersensibilité à la grippe. Le fait est d'autant plus interessant que pour d'autres infections les paludéens ont une réceptivité très grande.

M. AITAFF.—Etiology of Spanish Influenza.

Le pneumocoque et le bacille de Pfeiffer pénètrent par la même voie et en même temps dans l'organisme. Cette symbiose donne au bacille de Pfeiffer une plus grande vitalité et une plus grande virulence.

COURMONT, DURAND, DUFOUR.—Associated Organisms in Influenza.

1° Pneumocoque est rare; 2° le bacille de Pfeiffer constant dans les lésions pulmonaires, fréquent dans la gorge, ne se trouve pas dans le sang; 3° le streptocoque hémolytique ou viridance est associé aux bacille de Pfeiffer. Il joue un rôle capital dans la génèse des complications pulmonaires.

LOUIS MARTIN.—Diphtheria Carriers.

Le bacille diphtérique reste virulent après guérison apparente. Les convalescents de la diphtérie, comme ceux des diphtéries anormales, peuvent être porteurs de germes. Technique de la recherche de porteurs: On ensemence le sérum, soit par la spatule, procédé recommandé, soit par le tampon stérile, soit d'après le procédé Costa. Examen des colonies: Les tubes sont placés à 37°, les colonies sont bien développées après 24 heures ou 36 heures, elles sont d'un blanc grisâtre, sèche à la surface, à contour net, très arrondies. Les bacilles sont longs de 4–6 μ. Les extrémités arrondies sont plus grosses que le centre. Le bacille diphtérique prend le Gram, il présente aux deux extrémités des grains prenant fortement la couleur. Coloré par le Gram, le bacille diphtérique, âgé de 24 à 48 heures se décolore en 15 minutes dans l'alcool absolu. Sur gélose profonde, glucosée tournesolée, le bacille diphtérique fait virer au rouge le tournesol, il pousse en profondeur, ce qui le sépare du plus grands nombres de bacilles dits pseudo-diphtériques. La contagiosité des porteurs et des malades diminue avec le nombre et la virulence des colonies. Recherches des porteurs.—Porteurs précoces, commençant une diphtérie, porteurs anciens dits porteurs sains, peut être immunisés par une légère atteinte. La recherche et l'isolement des porteurs dans les collectivités de gens valides doit être recommandée. Les porteurs ne doivent être rendus à la vie commune qu'après deux ensemencements négatifs à 6 jours d'intervalles, les bacilles pouvant reparaitre. Traitement des porteurs, soit par attouchements de la muqueuse avec du sérum antidiphtérique, soit par la méthode sérothérapique, soit par inhalation de sérum en poudre, soit mélangé de sérum et d'arsénobenzol, soit par des cultures de staphylocoques dorés pulvérisés dans le larynx. Prophylaxie: isolement des porteurs et surtout des malades, desinfection, injection préventive.

DOPTER.—Meningococcus Carriers.

La morbidité de l'infection méningocoque est une de celle qui a paru négligeable dans la zone des armées. La cérébrospinale n'a sévi que suivant une mode sporadique, et les petits foyers d'infection se sont étients sur place. En temps de paix la "méningocoque" avait une grande puissance de diffusion et les porteurs dans le millieu de cérébrospinale étaient nombreux. Dans la zone des armées la rareté des porteurs est remarquable. Cela tient à ce que la densité de fronts a été peu élevée, et dans les dépots, où les troupes sont plus resserrées, le nombre restreint de porteurs semble en rapport avec la rareté de la cérébrospinale. Le porteur a joué un rôle de propagation limitée, mais qui entretient la graine spécifique. La prophylaxie consiste dans l'isolement des porteurs sains et des suspects. L'activité de laboratoire y contribue pour une large part.

LEVADITI.—Streptococcus Susceptibility of Wounds.

1° Une plaie, devenue streptococcique, réinfectée par le suc provenant d'une autre plaie streptococcique, à peu de chance d'infection. 2° il est de même lorsque la réinfection est faite par le strepto cultivé chez le blessé lui même. La réinfection a lieu si l'on se sert d'un strepto virulent d'un autre sujet.

Reviews and Notices of Books.

Dr. John Radcliffe: a Sketch of his Life, with an Account of his Fellows and Foundations. By J. B. NIAS, M.D. Oxon., M.R.C.P. Lond. Oxford: The Clarendon Press. 1918. Pp. 148. 12*s.* 6*d.*

Dr. Nias was Radcliffe travelling Fellow during the term 1882–5, and, as every pious beneficiary should, he has set himself the task of becoming acquainted with the life of his benefactor, with his foundations, and with the lives of his fellow beneficiaries. The results of his inquiries are embodied in the interesting little volume which lies before us. Radcliffe's foundations were two in number—namely, the Fellowships and the Library—but Oxford also owes to him, through the generosity of his trustees, the Radcliffe Observatory and the buildings of the Radcliffe Infirmary. The two latter foundations were not specifically provided for in Radcliffe's will, but the trustees were enabled to furnish the money owing to the falling in of annuities which had been paid to Radcliffe's two surviving sisters and sundry nephews and nieces.

It is unnecessary to say more here about the facts of Radcliffe's life than that he graduated in medicine at Oxford in 1675, being a Fellow not of his own College, University, but of Lincoln, that he proceeded D.M. in 1682, and that in 1684 he gave up his Oxford practice and went to London, where he speedily acquired a large practice. He was physician to Princess Anne, afterwards Queen, and to William III. and his Queen. He was a sound physician as far as knowledge went in his day, did not mince his words to his patients, was honest and upright, and made a large fortune, which he devoted by will entirely for the advancement of the study of natural science and medicine in connexion with the University of Oxford. The Radcliffe Fellowships were, according to the founder's regulations, two in number, tenable for the term of 10 years, not liable to forfeiture on marriage, and of the value of £300 per annum. The candidates had to be Masters of Arts, and "entered on the physic line"; but their professional training was to be obtained outside Oxford, for they were required to spend half at least of the 10 years in "travell in parts beyond sea for their better improvement." Such were the regulations of the original foundation. In 1858 alterations were made, the tenure of the Fellowships becoming a term of three years, while an election was made every year.

Dr. Nias's notes on his predecessors and successors in the Fellowship are all interesting, and there are incidents in the career of the first Radcliffe Fellow which we select to note. He was Dr. Noel Broxholme and was elected in July, 1715. In one of his Fellowship journeys he treated an opulent merchant in Paris, who gave as fee a draft for £500 Mississippi stock. On his return to London Broxholme found

the Mississippi Bubble in full swing and sold his £500 draft for £10,000. On another occasion he was called, together with Dr. Freind, to Ingestre to see a gentleman by name Pulteney. They found him in a desperate state and could only say that nothing could be done. The patient kept on murmuring, "Small beer, small beer." Freind and Broxholme wisely said, "Give him small beer or anything." So a large silver tankard was brought, holding two quarts, full of small beer, to which was added the juice of an orange. The patient drank the whole at a draught and called for another, which was given him. After drinking this he fell into a profound sleep, with profuse sweat, and continued so for 24 hours. "From that time he recovered marvelously insomuch that in very few days the physicians took their leave, saying that now he had no want of anything but of a horse for his doctor and of an ass for his apothecary." Soon after this St. George's Hospital was opened—1733—and Broxholme was elected one of the first physicians, Dr. Peters, another Radcliffe Fellow, being elected two years later. Dr. Nias adds: "We shall see that other Radcliffe Fellows were lured away from Oxford, so that Radcliffe's project began to fail of its intentions." Radcliffe had hoped that by his benefactions a race of well-educated physicians would be raised to practise and teach in Oxford, for he had arranged that during the tenure of the Fellowship his Fellows should reside in Oxford while in this country, two sets of rooms being reserved for them at University College, together with a seat at the High Table. But Oxford possessed no infirmary until 1772, so that Oxford medical men naturally went where there were opportunities for seeing clinical work. The end of the first Radcliffe Fellow was sad, his mental faculties decayed, and he committed suicide in 1748. The account of the Radcliffe Library and Infirmary, appended to Dr. Nias's biographies, are from the pens of the Librarian and Radcliffe Observer respectively, Mr. W. Hatchett Jackson and Dr. A. A. Rambaut. Altogether the book is a worthy memorial of one of Oxford's most generous sons.

Les Borgnes de la Guerre: Prothèse Chirurgicale et Plastique. Par Dr. G. VALOIS. Paris: Masson et Cie. 1918. Pp. 224. 12 fr.

THIS is an extremely interesting study of the treatment of those who have lost an eye in the Great War. The injuries of the eye have formed a proportion of wounds far in excess of any preceding war. The work of the ophthalmic centres has been correspondingly heavy. It is most important that the men who have suffered this loss should have the deformity concealed as far as possible. Therefore the treatment of the damaged lids, the preparation of the socket, the method of removal of the injured eye, when this is necessary, and the choice and adaptation of a prothesis are all of unusual moment.

Dr. Valois shows in great detail the methods which experience has taught him to adopt for the best cosmetic result, combined with the necessary caution to preserve the undamaged eye from risk. While it is most important to preserve all skin, when the lids are involved, and all conjunctiva, the author is strongly in favour of the complete removal of the injured eye. All attempts to leave a part of the sclerotic and use it as a means of improving the stump he condemns on the ground of the risk of sympathetic ophthalmia. He justly points out that the artificial eye is at best only a means to hide deformity; therefore it cannot be right to allow any patient to run the risk of total blindness from sympathetic inflammation of the fellow eye merely to improve slightly his appearance. There can be no question that this point of view is correct, and the sole cause for differences in practice is the different opinion held by ophthalmic surgeons as to the risk of sympathetic inflammation after such an operation as evisceration. Dr. Valois's view sharply contrasts with that put forward by Dr. Weekers in Vol. III. of the Practical Medicine Series reviewed below.

Dr. Valois speaks very strongly of the value of immediate attempts to reform the lids, as far as possible, even after severe shell injuries, by replacing the torn skin in position and securing it by stitches. These immediate operations often, he says, result in the happiest way, and always make future interference easier. For the purpose of increasing, as far as possible, the mobility of the glass eye, and lessening the deformity, he utilises a flap of sclerotic which had been removed from the excised eye, and to this he stitches the tendons of the recti. He thinks this is superior both to extraneous supports, such as Mules's spheres, or to autoplastic skin or cartilage masses.

The adaptation of the artificial eye to the socket forms the subject of the last half of the book. The socket after such wounds is rarely normal; Dr. Valois recommends that a cast in plaster be taken of each case and the eye adapted to this.

Diseases of the Eye. By J. HERBERT PARSONS, F.R.C.S.Eng. Third edition. London: J. and A. Churchill. 1918. Pp. viii.–668. 16*s.* net.

THE second edition of this well-known handbook was reviewed in these columns in June, 1912; that a new edition of a book which is but slightly connected with military surgery should be called for is a fact which speaks well of the general interest of the profession in the special departments. It has been in the past to some small extent a justifiable reproach to the profession that they appeared to neglect ophthalmic surgery and to regard it as a mystery revealed only to the few. The very real interest shown by the demand for such books as the one in review is in itself a proof that the reproach is no longer deserved.

It is inevitable that successful text-books should increase in size, and the enlargements of the present edition are considerable. They include a new section on symptomatic disease and additions to the operative and therapeutic sections; the preface also states that short accounts of less common diseases of the eye are added, distinguished from the main text by smaller print; this practice, which would assist in keeping the book of reasonable size, might, we think, have been extended with advantage. We doubt whether for a student's handbook any mention of ophthalmia nodosa—a disease of which some half-dozen cases are recorded—is desirable, yet this remains in large print; in fact, the small print has to be hunted for. Spring catarrh, again, will be seen by few general practitioners, yet it remains in large type and occupies more space than ophthalmia neonatorum.

It is easy to be critical, and extremely difficult for an author to avoid diffuseness; still, in a student's handbook we think the pruning knife should be used freely to excise those matters which are not likely to be met with in general practice. On the other hand, and, in fact, as a complement to this, the commoner diseases might have with advantage a little more detailed description. Thus a short account of Priestley Smith's experiments on glaucoma would have been very valuable to the student. There are a few points in the text which are obscure; for example, in the section on malingering, on p. 390, it is said that when the malingerer looks at Snellen's letters, which are printed in red, and with a red glass before the good eye, the good eye will see only the red letters; this is so if the letters are seen as a transparency, or if they are printed in colour on a black ground. If, as the text seems to imply, they are printed in colour on white, the eye with the red glass sees the green letters but not the red. The tone of the preface is a mistake.

The Practical Medicine Series. Vol. III.: *Eye, Ear, Nose and Throat.* Chicago: The Year Book Publishers. 1918. Pp. 384. $1.60.

THE section on the eye in this year book is edited by Dr. Casey Wood, who has increased its value by his comments on various papers included in abstract form. The war has been responsible for a diminution of writing on all subjects but itself, and the military surgery of the eye forms a considerable section of the present volume. Weekers is quoted as a strong advocate for evisceration of the eye in place of enucleation; he claims that this gives as complete security against sympathetic disease, and infinitely better cosmetic results. He has found sympathetic disease rare in all cases and attributes this to the common use of aseptic and antiseptic precautions from the moment of the receipt of the injury. Terrien, also, is quoted in favour of the retention of a "natural stump" for the support of the prosthesis. He considers that none of the methods for the attainment of such stumps are entirely devoid of risk of sympathetic disease; both he and de Lapersonne protest against the hurried removal of every damaged eye at the base hospital. There is little, if anything, to gain from immediate operation, and often an eye which appears totally lost may recover some little sight. This point is of special importance when both eyes are injured. Lastly, Dianoux protests against enucleation. He believes in the value of evisceration, and would never remove an eye except where it has been blown to pieces.

THE LANCET.

LONDON: SATURDAY, DECEMBER 7, 1918.

Demobilisation and Venereal Diseases.

PESTILENCE has invariably accompanied and dogged the footsteps of war, although not always the same disease has been the comrade and follower. We have had, and are still having, our experience of a devastating pandemic in the last year of the present war, and though many great epidemics of influenza have smitten populations in times of peace, the range and severity of the present one were, no doubt, the outcome of the war conditions throughout the world. We have been warned of the risk from lice-borne diseases that returning troops may bring to the civil population, and although that risk is one that can be guarded against with some certainty the medical profession know well of its existence. And now the fear of a wide spread of venereal disease is before the minds of those best able to judge of its likelihood. Are we ready to meet a massed attack of this sort should it be made? In an interesting book, published by the Carnegie Endowment for International Peace, Dr. F. PRINZING [1] recalls the far-ranging outbreak of syphilis at the end of the fifteenth century when the Landsknechte of Central Europe returned to their distant homes. We know more now—infinitely more; but let it be remembered that the facilities for intercommunication have certainly increased as much as our knowledge, while, alas, the public takes all the facilities greedily, but makes little use of the knowledge. Another historic outbreak of syphilis associated with CHARLES VIII.'s expedition to Naples in 1495 again resulted in wide dissemination over the whole of Europe. These are warnings not to be disregarded when Lord SYDENHAM, writing as President of the National Council for Combating Venereal Diseases, states that as many as 300,000 men of the Navy and Army may be under treatment for infective venereal disease at the moment. That such a figure should be in question removes the need of further urgent plea that defences should be set up. We must see that these are prepared promptly, but also carefully. It is not a time for panic legislation, of which we have already had something in the Regulation 40 D, which has now been suspended with almost universal approval.

That the demobilisation of armies should be attended by the spread of venereal disease among the civilian populations is an obvious likelihood. There must be present at such a time great inducements to sexual intercourse, regular or irregular. There is a large resumption of marital relations, there is a large number of young marriages, there is a large number of unions of a temporary nature, there are pent-up longings for natural expression, and relaxations of standard. The demobilised troops have been placed with regard to venereal infections at one and the same time very favourably and very unfavourably. So far as accident and as temperament dictate the incidence of venereal diseases among them, many have been precluded from the outlet of natural passion and may possibly find that they are able to restrain themselves at the instance of an acquired discipline. Many will not be able. This latter class, a certain proportion of whom are known to be dangerous males, will now, on demobilisation, be exposed in bulk to other sources of infection, and accident alone will determine whether the chances of infection which they exchange become rampantly present or fortunately absent, unless some scheme of prevention is prepared. The Government has been stirred by a debate which took place in the House of Lords at the end of November to consider strong measures of precaution. Lord SYDENHAM on that occasion solemnly warned the Government that if such measures were not taken quickly there would be serious results to the whole population extending over many years, adding that the necessary legislation had not been taken in time, and that an Act dealing with quack remedies was proving of no practical use. Lord MUIR MACKENZIE, who had presided over a Committee which took evidence on all these points, complained that the Committee was belated in appointment, so that no chance had been given for introducing a Bill embodying recommendations which it might make, but he urged the next Parliament to take up the matter in the light of the information now available. The fear is that nothing effective will be done for some weeks, as Parliament is now prorogued to make way for a General Election; but the feeling among medical men is that, while political machinery has disappeared from Westminster, the permanent Departments of Government are not rendered inactive thereby, but, on the contrary, may obtain a freer hand. The Local Government Board will be expected to be aware of the dangers which must arise from the release of a large number of infected men, and to be ready with arrangements for meeting the evil. The National Council for Combating Venereal Diseases have published recommendations which should be carefully considered by the Board, as by all other Departments which can make them their concern. One of these recommendations goes to the root of the matter, for it suggests that no sailors or soldiers should be discharged while in an infective state. They incurred the disease in the service of the country, and it is the business of the country to return them in as fit a condition as possible. The sense of this recommendation is obvious. The Navy and the Army have got the men in disciplinary clutch. They can effectively control them, they can watch their improvement stage by stage until they are safe members of society, and they can compel the measures necessary to this end. For the rest many treatment centres have been established in England and Wales at

[1] Epidemics Resulting from Wars. By Dr. F. Prinzing. Clarendon Press. 1916.

which infected citizens can obtain treatment in sympathetic circumstances at the hands of specialists, while at these centres the presence of the general practitioners of the neighbourhood is invited—we might almost say urged—so that as many medical men as possible should familiarise themselves with techniques which have evolved from comparatively modern medical science. Here is at once a direction in which the cure of the infected and the prevention of spread of disease can both be strengthened. These centres require immediate multiplication. Many Army doctors have now specialised in the treatment of venereal disease, and their services should be used in connexion with the establishment at large provincial hospitals of clinics for the treatment of venereal diseases. No town of over 10,000 inhabitants should be without one.

Although the difficulty of staffing the centres should now be relieved by the discharge from the Army of doctors who have become experienced in the treatment of venereal diseases, treatment is almost futile unless it is prolonged to complete cure, and the standard of cure remains to be set up. A powerful plea for more rigorous standards of cure in the treatment of gonorrhœa by Mr. E. R. TOWNLEY CLARKSON, which we published in our issue of Nov. 30th, will awaken the medical profession to an appreciation of the difficulties. We fear that among some medical men there is still the half-expressed dislike to treat venereal disease at all. There is the tendency for the practitioner who first sees the case to hand it on to another for treatment. The patient naturally is loath to advertise his condition, and the inevitable result is the postponement of treatment until cure is difficult or the premature cessation of treatment before it is complete. On the side of the public there is still a widespread ignorance with regard to the results of the disease and the tendency to regard it frivolously. The infected woman especially is often unaware that anything at all is wrong with her; a vaginal discharge to her is just the "whites," and is often regarded as a normal condition. Remedies of a palliative nature soon cause an abatement of her disturbing symptoms and lead to discontinuance of treatment and spread of disease. This is a position of far-reaching possibility for evil. To return to the spread of disease by men during demobilisation, every man on demobilisation should be investigated from this point of view, and not by cursory questions, but by routine methods. The record sheets will be a help to this end. Such men as have evidence of the disease should be segregated until they are cured. But the great difficulty remains. A man may be cured and be free, but it is the women, and not only those of easy virtue but the married women who remain as a menace. Quite a number of married women, it is known, have already acquired the disease in the absence of their husbands or from husbands who may have been since cured. The men can be easily dealt with, but how to cure the women is frankly a terrible problem. And if they are not being treated how to stop the spread? We have said that this is not the time for panic legislation, but it is exactly the time for speaking out, so that the people may understand. A popular campaign which should teach people the nature and danger of venereal diseases is a revolting idea to many—even to some doctors. The times should have altered such views. The incidence of both syphilis and gonorrhœa since the beginning of the war must be great; it is not limited to any particular class or to the usual ages. While it behoves the doctor to instruct himself in the treatment of venereal diseases, and the Government to find facilities for such treatment, the education of the general public comes only next in importance. The National Council for Combating Venereal Diseases have done much, but as yet there is little general response to the movement.

An Enemy Medical Boycott.

RECENTLY one of the two principal German medical papers[1] contained in its current notices the paragraph:—

"Das englische Fachblatt *Lancet* bringt seit kurzem eine französiche Beilage, die unter Redaktion von Prof. Ch. Achard und Dr. Ch. Flandin in Paris Beiträge französischer Verfasser in englischer Uebersetzung enthält."

And in so doing broke the silence of years in regard to quotation from our columns. German medical editors were free to receive THE LANCET during the war, and they certainly kept a close watch upon articles of a critical or antipathetic nature appearing in the medical press of this country. We need only recall the exchange of compliments following on Dr. J. P. ZUM BUSCH'S account of his internment experience at Stratford.[2] The *Muenchener*, like the *Deutsche*, has during the four years of hostilities, contained a small weekly paragraph (signed, in the case of the latter, with the editor's initials) summarising current events of the war. Comment has at times been bitter, especially in regard to such matters as the detention by the French authorities of captured German Red Cross personnel, and the alleged effect of the food blockade in bringing pressure to bear on mothers and children. The asperity has included the business management of the papers, an instance of which we may repeat. An inquiry made from Switzerland for the translation rights of a surgical war primer elicited from the publisher of the *Muenchener* a telegram to the effect that translation was futile, as the wounded and captured British soldier would be treated in *German* hospitals on the lines of the *German* edition. Note that the capture of the British soldier was assumed, and LEHMANN was known before the war as a prominent advocate of pan-Germanism. On the other hand, close study from week to week has failed to detect any kind of bitterness, or even tendenciousness, among the scientific articles appearing in the two principal German papers already named, or in the *Wiener klinische Wochenschrift*, the leading Austrian medical journal. The work of British, American, and French surgeons of note has been freely

[1] Münchener medizinische Wochenschrift, Oct. 29th.
[2] THE LANCET, 1916, ii., 331.

utilised and dealt with in an objective manner in these periodicals by professional writers. Where credit has been withheld, the omission has apparently been due rather to misinformation than to any desire to suppress. Probably not all Austrian clinicians and not all German professors read English as fluently as their own language.

Our professional relations and those of our Allies and of the United States to German medicine are not as yet easy to define. Some few straws indicate the direction of the current. A special commission has recently reported to the Paris Academy of Sciences on the international scientific relations which should rule after the war. The conclusions of this commission have just been adopted with *une forte majorité* by the Academy of Medicine. Both academies consider that personal relations between the *savants* of the two belligerent groups are impossible until reparations and expiations have been made. They suggest that the Central Empires should be obliged by the peace terms to retire from international scientific associations except in so far as indispensable services are concerned. And then navigation, railways, telegraphs, are catalogued as services in which we cannot dispense with German and Austrian coöperation, but neither public health, medicine in general, nor quarantine is mentioned. The immediate establishment among the Allies and the U.S.A. of new associations is contemplated with the addition of representatives of Neutral countries. The Allied Governments under this scheme would in future abstain from sending delegates to any meeting at which representatives of the Central Powers were present, while dispositions would be studied for an intimate collaboration between the several Allies and the U.S.A. in the whole domain of science. In similar mood, and at the suggestion of the Royal College of Surgeons of England, the Royal College of Physicians of London is considering the exclusion of German and Austrian universities from the list of schools accepted by the Conjoint Examination Board for certificates of study. An inter-Allied conference which met at Burlington House, London, on Oct. 9th called upon the scientific academies of the Allied nations to declare their inability to resume personal relations in scientific matters with the Central Powers until the latter have publicly renounced the political methods which have shocked the civilised world. Our own British scholars who published on Oct. 21st, 1914, a reply to the notorious manifesto of the 92 German professors admitted how hard it is for human beings to weigh justly their countries' quarrels, generously adding that they did not question for a moment the personal sincerity of their German colleagues in expressing horror at war and zeal for the achievements of culture. Our British scholars did more than this, and went on to record their real and deep admiration for German scholarship and science, and to acknowledge the many ties of "comradeship, respect, and affection" which bound them to Germany. We can imagine that some of these ties have lost their influence, and that for the time being German men of science will share in the general obloquy until some expression of real apology is forthcoming.

The term "boycott" has been applied by the daily press to the action contemplated above, but we foresee certain difficulties in regard to an enemy medical boycott. For clearness sake an exact definition is desirable. The methods employed against Captain CHARLES CUNNINGHAM BOYCOTT in the year 1880 were of a drastic character; his life was threatened, his fences torn down, his letters intercepted, and his food-supply interfered with. By British medicine this course has not been followed, and it will not be, as far as we can see. To take a simple example. The *Daily Review of the Foreign Press*, issued by the General Staff of the War Office, has not hesitated to make full use of German medical science. A recent instalment reviews at length the treatment of gunshot injuries of nerves in enemy countries, and gives medical, surgical, and pathological notes from German workers, with the object of providing useful comparison for our home workers. In fact, an influential section of the press recently made a bitter complaint against our own Local Government Board that it had not utilised to the full information available from this source. To those who have adopted such a course a boycott in medical matters would be a difficult thing to carry through logically. It could, in truth, only be practised by those who possess no knowledge of the German language nor any appreciation of what has been done by German workers. The attitude adopted by the War Office in its *Daily Review* does not imply the endorsement of the methods of famous Germans. We may all wish that LUTHER had been more reasonable, that KOCH had been more discreet, and that VON BEHRING had turned his researches less to immediate personal advantage. But this desire does not induce sensible people to boycott the Bible, tuberculin, or antidiphtheritic serum. No courageous person refrains from adhering to a cause because it is advocated by unpleasant people or in an intemperate manner. A study of contemporary German medical literature suggests no reason for not studying it; this done, the medical boycott will be found impracticable.

ALVARENGA PRIZE.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about $250, will be made on July 14th, 1919, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, but cannot have been published. They must be typewritten, and if written in a language other than English should be accompanied by an English translation, and must be received by the secretary of the College, Mr. Francis R. Packard, 19, South 22nd-street, Philadelphia, on or before May 1st, 1919. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. It is a condition of competition that the successful essay or a copy of it shall remain in possession of the College; other essays will be returned upon application within three months after the award. No Alvarenga prize for 1918 was awarded.

Annotations.

"Ne quid nimis."

MEDICAL REPRESENTATION IN PARLIAMENT.

THE last day for the nomination of Parliamentary candidates was Dec. 4th, and the following is a complete list of medical men who are standing:—

Universities.—Belfast (Queen's): Sir William Whitla. Dublin: Sir Robert Woods. London: Sir Wilmot Herringham. Scotland: Sir Watson Cheyne, Dr. Peter Macdonald, Principal W. R. Smith.

London District.—Bermondsey (West): Dr. Alfred Salter. Shoreditch: Dr. Christopher Addison. Southwark (Central): Dr. L. Haden Guest. Stepney (Whitechapel and St. George's): Dr. Robert Ambrose. Willesden (West): Dr. J. S. Crone.

County Boroughs.—Birmingham, Moseley: Dr. R. Dunstan. Leeds, North: Dr. A. C. Farquharson. Liverpool, Wavertree: Dr. Nathan Raw. Morpeth: Dr. T. M. Allison, Mr. G. D. Newton. Wallasey: Dr. B. V. P. McDonald. Wolverhampton, Bilston: Mr. J. W. Kynaston.

English and Scottish Counties.—Derby, High Peak: Dr. Clifford Brookes. Durham, Bishop Auckland: Dr. V. H. Rutherford. Hants, Basingstoke: Sir Auckland Geddes. Inverness (Western Isles): Dr. Donald Murray. Lancs (Farnworth): Sir Thomas Flitcroft. Stirling (Clackmannan and East Stirling): Dr. W. A. Chapple.

THE MEDICAL PARLIAMENTARY COMMITTEE.

THE Medical Parliamentary Committee has been working steadily during weeks which have been particularly exciting in political circles. The Committee sprang to life in response to a general feeling in the medical profession that the medical view is largely unrepresented in Parliament, and if its birth was too late to allow much to be done in respect of the General Election now upon us, it has accomplished work that may be of real value in the immediate future. The Committee has made inquiries through the country with regard to medical men willing to stand for Parliament, either now if their help is sought, or in the future as opportunity offers itself. The result of these inquiries has been the collection of information which will be of the greatest use in future elections, and in particular in by-elections, where it is more likely that a constituency may find itself suddenly willing to adopt a new candidate. The information which the Committee has received, and is receiving, will greatly help in the selection of Parliamentary candidates by being able to answer questions arising out of the candidate's views, circumstances and wishes alike. Everyone knows that there are candidates for Parliamentary honours who are pressed into the position by the public, and other candidates who are drawn into it by their personal desires and their hopes to do good, and yet others who feel that their particular profession is without adequate voice in the councils of the nation. In these divisions some men will be found to whom the expense to be incurred is of no consequence whatever, some to whom the expense is an absolute bar without full pecuniary guarantee, and the remainder who may or may not want assistance in varying proportions. It is of the very essentials of the work of the Medical Parliamentary Committee that all these particulars should be gathered without any regard to the party which the candidate will desire to support. The medical man in Parliament, as he is conceived by the Committee, is one who will follow the dictates of his reason with regard to party politics, if he wishes to, or if he must, assume a badge of that sort; but his grand duty in the House of Commons towards, not his profession nor his constituency, but the public, will be to uphold all legislation having for its object the improvement of the health of the people. As a selected medical man he will be able to do this with competency; he will have the medical profession outside the House of Commons as his colleagues, and he may expect from the Medical Parliamentary Committee indications as to when and how his voice should be raised. This is adumbrating for the Medical Parliamentary Committee a future of great usefulness, but such a future will only be obtained if now, while the Committee is in the making, the coöperative help of the whole medical profession is received for the movement. The Committee is offering to supply speakers wherever possible to any medical candidates for Parliament who may desire such assistance in the election. The time is short, and in order to facilitate arrangements the names of all medical men willing to render assistance should be sent immediately to the honorary secretaries of the Committee, Dr. Arthur Latham and Dr. Charles Buttar, care of the Committee, 20, Hanover-square, London, W. 1.

THE CONTRA-INDICATIONS OF RADIOTHERAPY IN CERTAIN FORMS OF CANCER OF THE SKIN.

RADIOTHERAPY constitutes a great advance in the treatment of many forms of cancer, but its limitations are not so well recognised as they should be. At a meeting of the Académie de Médecine of Paris M. J. Darier has done well in calling attention to the contra-indications of radiotherapy in certain forms of cancer of the skin. In many cases it brings about rapid cure without pain or mutilation, but in others it fails, and may even aggravate the disease, to say nothing of the dermatitis which may be produced by excessive doses. To explain these results errors of technique or in the estimation of the size and depth of the tumour have been invoked, but M. Darier does not agree with these explanations. He attributes unfortunate results of treatment generally to the kind of cancer treated. He divides cancer of the skin and mucous orifices into four classes. 1. The form which is curable by radiotherapy, tubular or baso-cellular epithelioma (rodent ulcer), the ordinary cancer of aged persons which never affects lymphatic glands nor causes metastases. It yields marvellously to a few séances of irradiation. If the tumour is budding and voluminous the greater part can be removed as a preliminary with a curette or otherwise. It is only in advanced cases when the ulcer has invaded bone or the cavities of the face that radiotherapy fails. 2. M. Darier holds that "lobulated or spino-cellular epithelioma," which is the usual form of cancer of the tongue and lips (smoker's cancer), of the external genitals and anus, and of the scar of lupus, should never be treated by radiotherapy. It rapidly infects the glands, and usually proves fatal in less than two years. The X rays or radium produces only apparent improvement for two or three weeks. Then proliferation is more active and seems to have been stimulated. Often a case operable at first becomes inoperable after radiotherapy. Excision as early as possible is the only treatment. 3. Radiotherapy is useless in melanotic sarcoma (nævocarcinoma), and means only loss of precious time. Surgical treatment, of which M. Darier

prefers electrolysis, is indicated. 4. There is only apparent advantage in treating by radiotherapy the small cutaneous growths secondary, for example, to cancer of the breast, whether operated on or not. In spite of their frequent disappearance under the influence of the rays the prognosis of the disease is in no way improved. Thus it is absolutely necessary when there is tumour or ulcer of the skin which appears cancerous to make an exact diagnosis of the kind of cancer. If the clinical signs do not establish this a biopsy and histological examination are indispensable. An exact diagnosis can thus be made and the question of radiotherapy decided, in his opinion, and it is one which must have great weight.

THE ROYAL MEDICAL FOUNDATION OF EPSOM COLLEGE.

THE circumstances of war have seriously handicapped beneficent work of all kinds throughout the country, and the benevolent side of Epsom College has suffered in common with other institutions whose object is to relieve distress. Not only have expenses increased in consequence of higher taxation and the rise in prices, but many annual subscriptions have been withdrawn or reduced in amount. Coincident with this reduction in financial power, more applications for assistance have been made as a direct consequence of the war. Already two boys whose fathers had been killed in action as medical officers have been elected to foundation scholarships, while Salomons Entrance Scholarships have been awarded to two other sons of medical men who had lost their lives in torpedoed vessels. In addition to providing education of the highest class for 50 necessitous sons of medical men, with maintenance, clothing, and pocket money, Epsom College gives pensions of £30 a year to 50 aged and impecunious medical men and their widows, work which deserves the fullest support of the medical profession. We commend to our readers the appeal of Sir Henry Morris, the treasurer of Epsom College and its Royal Medical Foundation, as well as the advertisement, which will be found in other parts of the present issue of THE LANCET. In that appeal it is stated that if the number of beneficiaries are to be maintained £4500 must be procured in annnal subscriptions. We beg that this urgent need will be generously met.

LEGITIMATE WARFARE.

WE have become used to maiming and mutilation as a necessary—one may almost say a legitimate—result of warfare. The use of noxious gases producing death by asphyxia from pulmonary irritation has been a novel feature of the recent war, although the poisonous effect of lyddite fumes has been known for a longer period. The battlefield has been heretofore in essence a septic surgical ward; the most distressing conditions with which the physician has to deal have now been superadded. A letter appeared in the press last week signed by the Presidents of the medical Royal Colleges of the United Kingdom and by the Regius professors of medicine of the older Universities, asking that gas warfare should be abolished by the coming Peace Conference as a weapon of offence. The use of gas, the signatories justly contend, is condemned for three reasons: (1) That it is an uncontrollable weapon whose effects cannot be limited to combatants; (2) that it is an "unclean" weapon condemning its victims to death by long-drawn-out torture; (3) that it opens the door to infinite possibilities of causing suffering and death, for its further development may well lead to the devising of an agent which will blot out towns and even nations. The letter deplores the devotion of the best efforts of science to devising more and more potent methods of causing death by chemical agencies. No two opinions can exist in regard to the abolition of gas warfare. The difficulty which confronts any Peace Conference is similar to that of limiting the activities of the mad dog; if allowed to bite at all the possibilities of harm are infinite.

THE NATIONAL IMPORTANCE OF GLASS-WARE.

THE importance of giving every possible encouragement to the glass industry, and particularly the scientific glass industry, in this country must be recognised when we reflect that the development of practically all industries depends primarily on the progress made in the laboratory. Here new processes can be developed, and here only can the means of utilising waste products be discovered. In addition to the laboratories for industrial purposes, there are the medical and research laboratories attached to the hospitals, the county and municipal laboratories in the public health services, and the laboratories in the universities, colleges, schools, and technical institutes, all of which use special glass apparatus. On the outbreak of war the country was faced with a serious shortage of chemical glass-ware, the only sources of supply in most classes of articles being the stocks of enemy-made apparatus held by the merchants in this country; and but for these stocks the situation, we understand, would have been disastrous, as there were no existing facilities for manufacture. We learn now that the British Chemical Ware Manufacturers' Association is appealing to the Inter-Departmental Glass Trades Committee of the Ministry of Munitions for practical help, and it is to be hoped that, in the interests of scientific research and industrial progress, their petition will receive very serious consideration, and ultimately be granted on terms which will give the industry a good start and keep it flourishing in this country.

TRIAL AND RE-TRIAL OF THE WASSERMANN TEST.

THE Wassermann test is one of the most complicated technical methods ever applied to diagnosis in medicine. It is difficult to believe that the technique will ever be mastered by more than a select few of the medical profession. At the present time even the principles on which the test is based are a sealed book to most men in clinical practice. The value of the Wassermann test has consequently to be taken largely on trust and the Medical Research Committee has performed a grateful task in submitting records[1] from which any careful reader will be able to form his own opinion of the clinical value of the test. We need hardly remind him that the reputation of the test depends upon three quite independent factors: the laboratory technique, the personality of the pathologist (if so we may call him in brief), and the accuracy of the clinician upon whose diagnosis the results of the pathologist are judged. No trial of the test is fair in which these factors are jumbled together. Many ways suggest themselves

[1] The Diagnostic Value of the Wassermann Test. Special Report No. 21 of the Medical Research Committee. 1918. Price 1s.

to the mathematical mind of testing them independently. The Research Committee's report notes the rather surprising neglect in the past of the precaution of controlling the value of the Wassermann test by demonstration of the *Spironema pallidum* or by pathologico-anatomical study of the material obtained on biopsy or autopsy. Clinical diagnosis is at best a comparative estimate of probabilities liable to be reversed by an accurate scientific method. The trial set up by the Committee and recorded in Special Report No. 21 took the form of obtaining samples of certain serums taken by an experienced clinician, A, from cases judged by him to be (*a*) certainly syphilitic, (*b*) doubtfully syphilitic, and (*c*) clinically non-syphilitic, and submitting these samples to three well-known laboratory directors, B, C, and D, and comparing the results obtained. One hundred and four specimens were thus submitted without clinical details, and the report records in parallel columns A's clinical data and the results of the Wassermann test as given by B, C, and D respectively. Each pathologist has his own method of recording results, but in all "positive" and "negative" are the two extremes, and it is the intermediate grades of certainty which are differently expressed. The report contains A's judgment on B, C, and D's results; it may be remarked, in passing, that the chemical sign $\rightleftharpoons$ is applicable here, and that B, C, and D might have been asked to judge A's findings. Comparing the technique of B and D, A finds remarkably close results, the only important divergence being in a case of carbuncles "clinically non-syphilitic" (A's auto-judgment) returned by B as positive (middle grade), and by D as negative. C returned the same case as positive. In three "syphilitic" cases (all treated) D's technique appeared more sensitive than B's, while in three other "syphilitic" cases (all treated) B's reaction suggested a greater sensibility than D's. C's results are not so close and differed from the clinician's diagnosis in several instances, some of which were important clinically. Apparently (the note is not A's, but added by the Committee) in five of these divergent results some defect existed in the laboratory technique on one particular day, for the serums subsequently re-tested in C's laboratory gave results substantially coinciding with those of B and D. Another divergent result of C rested (Committee's statement) upon a simple clerical error. The results as set out in the report should be closely studied by all who are interested in making empirical medicine scientific. The Research Committee asks readers to draw their own conclusions, adding:—

> The Committee consider that in the hands of those whose previous record entitles them to be considered as experts the percentage of positive Wassermann reactions in active syphilis is so high that the test may, for all practical purposes, be looked upon as specific.

The warning then follows:—

> It cannot be expected that this, or indeed any similar biological test, should invariably reveal the presence of some particular disease. The diagnostic value of any such test may be impaired, either by the imperfection of the test itself, or by some failure in its performance, or by idiosyncrasy of the patient, whereby he may fail to react characteristically.

We have no doubt that the reader's opinion will follow the Research Committee's lead. The practitioner has obtained a guide to clinical practice, but not an infallible one. In sending a specimen to be examined at a laboratory the clinician is not immune from possible failure at any stage. His clinical acumen may be at fault; the patient may have an idiosyncrasy; the specimen of serum may be improperly taken; it may be damaged during transport to the laboratory; the laboratory technique may be at fault; clerical errors may slip in; the result may be communicated in ambiguous form. In all these directions a high standard is essential and improvement is possible and, indeed, desirable. But the investigation conducted by the Research Committee will impress upon the minds of the profession as a whole the high value already placed upon the Wassermann test by the comparative investigations of C. F. Craig, of P. Fildes and R. J. C. Parnell, of H. M. Turnbull, of Uhle and Mackinney, and numerous others mentioned in the historical survey which precedes the report.

BREAD: HEALTH VERSUS CUSTOM.

WHOLEMEAL bread, with 80 to 90 per cent. of the wheat grain utilised, was introduced by the Ministry of Food during the war as a result of the pressure of submarine piracy. Stern necessity dictated the measure, but the scientific advisers of the Ministry were, nevertheless, expressing an unbiassed opinion in pointing out to the public the advantages which they gained from wholemeal extraction. Necessity past, these advantages still remain. Some part of the public, however—a large part, for ought we know—prefers white bread. Many reasons are alleged for this preference, but custom pure and simple probably plays the chief share in it. Young people of the educated classes are practically innocent of any such preference. So soon as it ceases to be necessary to extract from the wheat grain all the contained nourishment available for human food we may assume that the reactionary part of the public will return with a sigh of content to white bread as we knew it before the war. Unfortunately, they will be joined by others whose experience with war bread has accidentally been unhappy. It is true that palatable bread could be, and was, made from war flour. The mixing and baking, however, differed materially from that required for white flour, and many a baker failed to attain proficiency. Nor was this entirely the baker's fault, for the wheat was diluted with varying quantities of "other cereals," so that it needed variable treatment. But the baker was not told the composition of the flour and had to go by rule-of-thumb with each new batch as it was supplied to him. Better bread could have been made with better knowledge, but we deprecate the use of the phrase "better bread" to describe the return to whiter flour. Those with a taste for such bread may consider it "nicer," but it is elevating personal predilection on a pedestal to make it the standard of goodness. We still read in old books of one man wearing a "better" coat than another, the word having no relationship to the warmth of the coat, and in this sense perhaps "better bread" may stand. Of course, the *economic* necessity of the transitional period between war and peace may dictate the surrender of 18,000 tons of "offal" weekly to farmers, pig-keepers, and others in order to feed their animal stock; hence an economic argument for white flour. The public is somewhat in the position of the prodigal who was fain to share the husks with the swine. But certainly no advantage to the *health* of the community can be claimed in purposely producing husks, or so-called "offal," from wheat to feed animals. It would be better to

continue to extract 80 per cent. or more from wheat for the use of man, and to use other cereals, not needed for man, to feed stock. Medical men should continue to point out the virtues of wholemeal bread in order that the public may ask for it, in which case they will get it. The experimental work done during the war has demonstrated for all time the superiority of wholemeal over white flour for healthy people, although the war bread as actually purveyed to the public was not always nice. Thus instructed, it will be the fault of the public if it returns to the old over-refined white flour.

AMERICAN HELP IN FRENCH PUERICULTURE.

A LARGE part of the October issue of the *American Journal of Diseases of Children* is devoted to the work of puericulture in France, which has recently been a chief concern of the Children's Bureau of the American Red Cross. To its agency is due in goodly measure the relief of the serious situations created among French mothers and children through the displacement of the northern population of France, the general lack of medical attention, and the shortage of appropriate food and fuel. To take a single example, the city of St. Etienne, with a pre-war population of 180,000, had 120 practising physicians; now the 250,000 inhabitants depend on the services of 14 practitioners. Most villages have been entirely without medical aid since the mobilisation. The American Red Cross has taken a large share in the management of the child *rapatrie;* it has devoted its best efforts to the reduction of infant mortality, it has promoted clinics for pre-natal care, it has given aid to expectant and nursing mothers and their nurslings, and worked out plans for protecting young girls and for promoting social hygiene. Educational work has been a feature of the campaign. An exhibit of child-welfare work staged at Lyons drew an attendance of more than 170,000 persons in three weeks. All available forces—Governmental, philanthropic, and medical—have united in a preventive educational campaign, the results of which are likely to be of permanent value.

"I.K." TREATMENT IN TUBERCULOSIS.

Dr. Carl Spengler, whose progress in tuberculin therapy has been punctuated by a series of preparations, such as P.T.O., A.T.O., P.E., T.B. vaccine, P. vaccine, K.V., W.V., has now published in conjunction with Dr. H. Wassitsch, in the *Correspondenz-Blatt für Schweizer Aerzte* for Nov. 9th, an analysis of 484 cases treated by "I.K." A critical survey of the already bulky literature about this preparation of Dr. Spengler's was recently published by Dr. N. Robertson,[1] whose own advocacy of the remedy was not enthusiastic, his attitude being rather one of benevolent neutrality. The 484 cases now under review were taken from Dr. Spengler's private ambulatory clientèle at Davos up to 1914. The patients were given a rapid course of "I.K." treatment, the duration of which was 90 to 150 days, with an average of 130 days. A comparison with the results obtained by two other institutions, the Deutsche Heilstätte, in Davos, and the Deutsches Haus, in Agra, shows that though the duration of treatment was considerably longer in these institutions (226 and 179 days respectively) the results were in several respects inferior. In the matter of disappearance of fever Dr. Spengler's series was, indeed, inferior to that of the Deutsche Heilstätte, but while only 23 per cent. of the patients ceased to expectorate tubercle bacilli in this institution, and only 14 per cent. in the Deutsches Haus, this success was achieved by 42½ per cent. of Dr. Spengler's patients. The comparison of these three series with each other seems open to criticism in many respects. Dr. Spengler's patients enjoyed a most varied treatment, that by "I.K." being extensively supplemented by graduated physical treatment, by iodine and organic blood preparations, and by symptomatic treatment—e.g., narcotics for coughs. On the other hand, the patients of the Deutsche Heilstätte series, though cited as a standard for comparison, appear to have undergone percutaneous "I.K." treatment. A more instructive feature of this paper than the many elaborate tables it contains is Dr. Spengler's retrospect of his long and varied tuberculin career. Starting as an enthusiastic advocate of Koch's tuberculin treatment, he came more and more to realise its limitations and dangers, and to foresee that, in spite of certain merits, tuberculin was unsuited for general use. Hence his efforts during the past 10 years to produce a "fool-proof" preparation suitable for almost indiscriminate wholesale use in tuberculosis. And, he maintains, these and other requirements are fulfilled by "I.K." The evidence, however, is not so conclusive as we are invited to believe.

[1] We reviewed this book in THE LANCET, 1918, i., 144.

THE RELEASE OF ALCOHOL AND GLYCERINE.

DURING the week the Ministry of Munitions notified that there are now supplies of alcohol available for industrial purposes, and that manufacturers should be able to obtain their requirements from the recognised sources without restriction, subject to the regulations of the Board of Customs and Excise. Methylated spirit is also again available for public use, and glycerine, it is announced, should be procurable in a few days in substantial quantities through the ordinary retail channels. This notification will remove many of the disabilities which manufacturers have experienced through the withdrawal of alcohol, and pharmacists through the withdrawal of glycerine. It is to be hoped that, for example, our research organisers will be given special facilities in regard to the use of alcohol, or they will remain at much disadvantage owing to the liberal allowance of this commodity given in continental countries. The "fine chemicals" industry is a case in point.

Sir George Newman's annual report as chief medical officer of the Board of Education will be studied with keen interest by educationists and hygienists alike. The School Medical Service is integrally part of the public system of education, and must remain so, however correlated it may come to be with other health services. The report appears at the moment when this correlation is being intensively discussed, and we reserve comment for a future number, after the many important points raised have been duly weighed.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—An ordinary meeting of this society will be held to-day, Friday, Dec. 6th, in the society's rooms, West London Hospital, at 8.30 P.M., when a paper will be read by Dr. F. J. McCann, entitled "Treatment of Some Common Ailments of Women."

PUBLIC HEALTH IN ENGLAND AND WALES:

REPORT FOR 1917 OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

IN issuing his recent report on public health in England and Wales Sir Arthur Newsholme takes occasion to review the history of sanitation since the inauguration of the Local Government Board in 1871. He acknowledges the improvement in the nation's health which has occurred in the last 48 years, and rightly attributes it to the labours of our urban and rural authorities. He is, however, careful to regard it as an incentive to efforts for further progress.

Lessened Mortality and Morbidity since 1871.

The extent of life-saving achieved in recent years appears from the official statement that "more than a quarter of a million fewer persons die annually than would die if the experience of the decennium 1871–80 continued. This implies an enormous annual saving of sickness and disability, of loss of wages, of the production of dependent widows and orphans, &c." It is notorious that sickness is one of the chief causes of poverty. About 30 per cent. of the paupers in receipt of relief are on the sick-list; and the Royal Commission on Poor-law affirms that at least half of the total cost of pauperism is swallowed up in direct dealings with sickness.

The saving of human life effected during recent years may be shown by contrasting the mortality at different ages in 1911–15 and 1871–80 respectively. At all ages up to the forty-fifth year there has been a reduction in the death-rate of from 40 to 50 per cent.; whilst at all other periods of life a substantial decline in the death-rate has been secured. By the use of life tables the improvement in life prospect may be demonstrated. For instance, we learn that between 1871–80 and 1910–12 there has been an increase in the average expectation of life equal to 10 years among males, and to nearly 11 years among females.

The average annual deaths in England and Wales during the period 1910–12 were fewer by 234,955 than they would have been had the population been subject to the death-rate of the period 1871–80. And the persons whose lives were saved each year had, in accordance with the life-table experience of 1910–12, the prospect of living in the aggregate 9,612,600 additional years of life. About 64 per cent. of this salvage is attributable to reduced mortality from acute and chronic infectious diseases, including the common infectious diseases, tuberculosis, and respiratory affections.

A Ministry of Health.

The war has aroused national interest in the public health and stimulated criticism of existing machinery for its promotion. Consequently the fact that a vast residue of avoidable loss of life and health still remains unredressed is very properly brought to the notice of the responsible authorities. In this connexion the medical officer discusses the merits of the public demand for the consolidation, in a central bureau, of all matters concerning public health and local government. The desirability of establishing a supreme authority on these lines is generally recognised, and has already been contended for in THE LANCET, as the only means of ensuring efficient sanitary reconstruction after the conclusion of peace.

The recent appointment of Sir Auckland Geddes to the presidency of the Local Government Board, and thereupon the prompt presentation to Parliament of a Bill for the creation of a Ministry of Health, are, therefore, matters of considerable significance.

Imperfect Statistics as to Incidence of Disease: The Birth- and Death-rates.

In comparing the vital statistics of the present with the past we are, unfortunately, limited to the evidence afforded by the Bills of Mortality. Of the misery and suffering (short of fatality) inflicted by the common infectious diseases there was no reliable measure prior to 1899, in which year notification became generally compulsory. And even now there is no record of the mass of non-infectious diseases "not unto death," which, nevertheless, entail terrible suffering among the poor. Nor are any statistics of the sickness treated in public institutions as yet available for the purposes of preventive action.

In the medical officer's judgment the best index of combined social and sanitary progress is the death-rate among young children, and he gives interesting tables showing the national gain in child-life.

In the year 1914 the *national birth-rate* was 23·8 per 1000 of the population, but in 1917 it had fallen to 17·8, the number of births in the later year being fewer than in the earlier by 210,756. The birth-rate of 1917 was only half that of 1874, and even in 1913 it was only one-third lower than in 1874. The problem, however, is not only one of birth-rate but also of survivors—in other words, of excess of births over deaths. A tabular estimate of this is now published, from which it appears that the survivors from the risks of early childhood bear a steadily decreasing proportion to total population, being at the rate of 27·1 per 1000 in 1874 and 19·6 in 1916. Unless compensating influences come into play the population, apart from immigration, will eventually become stationary, the birth-rate not more than counterbalancing the death-rate.

The *national death-rate* is subject to severe limitations in respect of further reductions, although these limitations are still remote. A large portion of the mortality in childhood, in adolescence, and in adult life is certainly preventable. Failing the recruiting of our population by births, the possibilities of compensation by a lowered death-rate are limited by natural laws, and the future must be regarded with apprehension. A stagnant population—if it be approached within the next 20 years—will have momentous effects in this country, and will imply also the possible failure to people Great Britain with a race having the ideals of our civilisation.

Maternity and Child Welfare.

Calculated in the usual way, infant mortality in England and Wales during 1917 was 97 per 1000 births, against 91 in 1916—the lowest rate on record. But it has been pointed out that the births in a given year do not fairly represent the numbers among whom infant deaths occur, because of the rapid decline of the birth-rate. And it is found that when allowance is made for this fact, and the deaths are calculated *on the living at ages under 1 year*, instead of on the births in each year, the infant death-rate becomes 94 per 1000 births in 1917, against 98 in 1916 and 104 in 1912. The fall in infant mortality is the more surprising in view of the increasing number of women with young children who have taken up industrial work.

The experience of 1917 and of recently preceding years encourages the belief that we may anticipate a reduction of infant mortality to 50 in 1000 births—a rate which has already been attained in some parts of this country, and in New Zealand as a whole. If a more rapid decline of infant mortality in the first month after birth can be secured in the next few years this encouraging figure may be surpassed. But this can only be attained by improving the welfare of mothers generally. The conditions of improvement are abstinence from excessive fatigue in pregnancy and during the period of breast-feeding, and the provision of skilled medical care and nursing for both mother and offspring. For the attainment of these ends the Board's grants in aid of such objects are available.

Continued Decrease in Enteric Fever.

With reference to the medical officer's opinion that the best index of sanitary progress is furnished by the extent of enteric fever prevalence, we note that the decline in this disease experienced in recent years was continued in 1917, the number of notified cases of enteric fever being fewer by 963 than in the year preceding. Whilst recognising this success, it must be remembered that the demands of military service have entailed the withdrawal from civil life of a large number of men at ages of special susceptibility to enteric infection. Nevertheless, there are reasons for believing that the recorded fall is a real one.

The nature and variety of the circumstances attending enteric fever outbreaks are constantly being investigated by the Board's medical staff, and in this report attention is specially directed to a recent outbreak involving 133 cases in the Bedlingtonshire Urban District of Northumberland. This attack, which affected 11 villages, was traced by Dr. J. R. Hutchinson to the water-supply from the river Blyth, which had become specifically contaminated by the manuring of riparian land with midden privy refuse. The river water had been treated by sand filtration. The working of the filter was essentially faulty, and there was no

appreciable storage of the water either before or after filtration. This incident is valuable as showing that filtration alone cannot be relied on to render harmless specifically infected drinking water. In concluding his instructive report on this serious outbreak Dr. Hutchinson remarks that the use of midden contents for the manuring of agricultural land on the river bank is a process which has gone on week by week for more than 30 years, and is the only operation of etiological significance which is continually being repeated. It is reflected, he holds, in the recurring small explosive outbreaks of enteric fever which are to be found every year in the Bedlingtonshire District, and in the present year in the larger outbreak.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

The Statistical Report on the Ordinary Expenditure of 108 London Hospitals for the Year 1917 (issued at 1s. by Messrs. Spottiswoode, Ballantyne, and Co., London) indicates a great increase of the work of the London hospitals during the year under notice, with a corresponding increase in expenditure. This, as the honorary secretaries of the Fund point out, constitutes an enlarged and very urgent demand upon the voluntary subscriptions of the charitable public, and renders it more than ever important that this Fund and the Hospital Saturday and Hospital Sunday Funds should be enabled to increase their grants. London provides a total of 11,729 beds in average daily occupation, the total number of in-patients admitted during the year 1917 being 147,598, while 1,152,022 attendances were recorded in the out-patient departments. Out of the total of 147,598 in-patients, 28,031 were naval and military patients treated by understanding with the authorities and representing an average for the whole year of 3656 occupied beds, or 31 per cent. of the total average of occupied beds. One result of this has been the reduction of the number of beds available for civilian patients by 1659. The total ordinary expenditure during the year, including maintenance, administration, rent, rates, and taxes, but excluding capital expenditure, interest on borrowed money, and contributions to the maintenance of convalescent homes and country branches, amounted to £1,719,030. The receipts from the authorities for naval and military patients were £268,960. After deducting this from the total outlay there remains £1,450,070 to be met out of the normal sources of hospital revenue. From a comparison of the figures with those of last year the conclusion is drawn that the addition to the net annual expenditure has been caused almost entirely by the rise in cost of all items of maintenance. The report sets out in tabular form general particulars of work and accommodation of the various hospitals, together with an analysis of the cost of working.

URBAN VITAL STATISTICS.

(Week ended Nov. 30th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 36·5, against 38·7 and 36·3 per 1000 in the two preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 32·8 or 4·0 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 8·3 in Bootle, 12·3 in Cardiff, and 12·8 in Oxford, to 77·7 in Stockton-on-Tees, 78·6 in Grimsby, 83·0 in Walsall, 86·7 in South Shields, 91·2 in Sunderland, and 100·2 in Nottingham. The principal epidemic diseases caused 220 deaths, which corresponded to an annual rate of 0·7 per 1000, and included 60 from infantile diarrhœa, 51 from measles and from diphtheria, 35 from whooping-cough, 17 from scarlet fever, and 6 from enteric fever. Measles caused a death-rate of 2·8 in Wolverhampton, and diphtheria of 1·7 in St. Helens. The deaths from influenza numbered 5119, against 5106 in the previous week, and included 942 in London, 388 in Birmingham, 374 in Manchester, 272 in Nottingham, 166 in Sheffield, 151 in Sunderland, 120 in Bradford, and 118 in South Shields. The 1136 cases of scarlet fever and 1014 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 13 and 48 below the respective numbers remaining at the end of the previous week. The causes of 117 deaths in the 96 towns were uncertified, of which 23 were registered in Birmingham, 19 in Nottingham, 10 in South Shields, and 6 each in Liverpool and Sunderland.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 23·7, against 23·9 and 24·3 per 1000 in the two preceding weeks. Of the 1094 deaths from all causes, 47 were classified to influenza, which was also stated as a contributory cause in 212 deaths classified to other diseases; in the previous week these numbers were 29 and 252 respectively. The 465 deaths in Glasgow corresponded to an annual rate of 21·8 per 1000, and included 5 each from diphtheria and infantile diarrhœa, 4 from whooping-cough, and 1 each from measles and scarlet fever. The 206 deaths in Edinburgh were equal to a rate of 32·2 per 1000, and included 4 from whooping-cough, 3 from diphtheria, and 1 from infantile diarrhœa.

Irish Towns.—The 199 deaths in Dublin corresponded to an annual rate of 26·0, or 5·9 per 1000 below that recorded in the previous week, and included 49 from influenza and 1 each from whooping-cough, diphtheria, and infantile diarrhœa. The 463 deaths in Belfast were equal to a rate of 61·4 per 1000, but included no deaths from the epidemic diseases other than influenza.

The War and After.

THE CASUALTY LIST.

THE names of the following medical officers appear among the casualties announced since our last issue :—

Previously reported Missing, now reported Presumed Killed.

Capt. H. W. White, R.A.M.C., qualified in Ireland in 1910, and at the time of joining up was assistant medical superintendent at the Paddington Infirmary, London. Previously he had held appointments at the Long Grove Asylum, Epsom, and at the Metropolitan Hospital.

Died.

Major H. W. Sykes, R.A.M.C., was educated at Durham and qualified in 1909. Prior to joining the R.A.M.C. he was on the medical staff of the Randfontein Estates Gold Mining Co. in the Transvaal, and was previously medical superintendent at Grey's Hospital, Pietermaritzburg.

Capt. B. W. Cherrett, East African Medical Force, was a student at St. Bartholomew's Hospital, London, and qualified in 1906. He held an appointment at Plaistow Hospital, and prior to going on service was medical officer of health at Nairobi, East Africa, where he died of pneumonia following influenza.

Capt. G. L. Maule, R.A.M.C., was educated at Shrewsbury and at Cambridge, and qualified in 1916. Prior to joining the R.A.M.C. he was for some time house surgeon at the Manchester Infirmary.

Capt. P. S. Green, R.A.M.C., qualified at Manchester in 1911, and prior to joining the R.A.M.C. was in practice at Lowton, Newton-le-Willows, Lancs.

Capt. S. W. Matthews, R.A.M.C., qualified in Ireland in 1913, and prior to joining the R.A.M.C. was in practice at Wicklow.

Surg. Lieut. W. H. Pickup, R.N., was educated at Birmingham University, and qualified in 1915. He joined the Navy shortly afterwards, and died of pneumonia following influenza.

Capt. W. E. Paterson, New Zealand M.C.
Major R. C. Irvine, R.A.M.C.
Capt. C. R. Lister, Australian A.M.C.
Surg. Sub-Lieut. E. A. Pearson, R.N.V.R.
Surg. Sub-Lieut. T. Carlyle, R.N.V.R.

Wounded.

Major H. D. Lane, M.C., R.A.M.C.
Capt. H. R. Lawrence, South African M.C.
Major F. Henderson, M.C., R.A.M.C.
Capt. G. W. Mitchell, R.A.M.C.
Lieut. R. R. MacGregor, R.A.M.C.

OBITUARY OF THE WAR.

JOHN MORRIS, M.B., F.R.C.S. EDIN.,

MILITARY CROSS,
MAJOR, ROYAL ARMY MEDICAL CORPS.

Major J. Morris, who was killed in action in France on Oct. 7th, at the age of 39 years, was fourth son of T. Morris, J.P., of Oswestry. He graduated M.B., Ch.B. at Edinburgh University in 1904, after which he held posts as house surgeon at Denbigh Infirmary and assistant surgeon at Dinorwic Quarries Hospital, Llanberis. After obtaining the F.R.C.S. Edin. in 1909 he settled in practice at Hyde (Cheshire), where he became police surgeon and recruiting medical officer. In 1912 he joined the Territorial Force and was mobilised on August 4th, 1914, going to France with the Cheshire Regiment in the following November. In 1916 he was awarded the Military Cross, and his superior officer writes of him as a valuable surgeon. Major Morris leaves a widow and two children.

LOUIS P. DEMETRIADI, M.D. DURH., F.R.C.S. EDIN.,

LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS (T.).

Lieutenant-Colonel L. P. Demetriadi, who died at Southport on Oct. 26th, was 56 years of age. He was educated at Manchester Grammar School and King's College, London, and later attended Leeds University, taking the degrees of M.D. Durh., F.R.C.S. Edin., and D.P.H. He was house surgeon to the Huddersfield Royal Infirmary, and later carried on general practice in the town, retiring in 1912. For more than 20 years he lectured and trained classes for the St. John Ambulance Association, and acted as judge at various railway and colliery competitions. In 1916 he was made an honorary associate of the Grand Priory of the Order of the Hospital of St. John of Jerusalem in England. In 1897 he joined the 2nd Volunteer Battalion, Duke of Wellington's Regiment, and rose to the senior rank in its medical service. When the West Riding Territorial Division mobilised in August, 1914, he proceeded with it to France in April, 1915, taking charge of the West Riding (49th) Casualty Clearing Station, where he remained for two years, until his health gave way. Returning to home service, he received the Territorial Decoration, and then had to relinquish his commission owing to continued ill-health. He was twice mentioned in despatches. One of his superior officers writes of Colonel Demetriadi: "He was one of the most helpful officers I had working with me, and I knew that nothing was too difficult for him to carry out." He was active in the discharge of his civic duties, both as a member of the local municipal council and as a churchwarden. He married a daughter of the late Dr. J. R. Parke, of Tideswell, who survives him.

DIGBY BURNS, L., L.M. R.C.P. & S.I.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain D. Burns, who lost his life on the ill-fated *Leinster* while returning to duty on Oct. 10th, was youngest son of John William and Elizabeth Burns, of Dublin. He was educated at Mountjoy College, Dublin, and at the Royal Colleges of Physicians and Surgeons, obtaining the conjoint Irish diplomas in 1912. Shortly afterwards he was appointed house surgeon to Bootle Borough Hospital, where his personal qualities made him a popular colleague. After this preparation for general practice in 1913 he settled down at Orrell Park, Liverpool, and had acquired a considerable practice when in 1916 he received a commission in the Royal Army Medical Corps. His captaincy was conferred in the following year. His commanding officer writes of Captain Burns as the life of the little community in which he was placed. "His never failing good humour and kindly disposition endeared him to us all."

Captain C. D. HAMILTON, Lieutenant R. H. LALANDE, and Lieutenant W. McL. MCLEOD, all C.A.M.C., died on the voyage from Canada to England between Oct. 6th and 10th.

CHARLES WILLIAM DUGGAN, M.B., C.M. EDIN.,

MAJOR, ROYAL ARMY MEDICAL CORPS.

Major C. W. Duggan, who lost his life on Oct. 10th, at the age of 52 years, by the sinking of the *Leinster*, was only son of the late William Nelson Duggan, M.D., of Edinburgh, Major, A.M.S. He was educated at Daniel Stewart's and George Watson's Colleges and graduated at Edinburgh University in 1887, was assistant to the professor of medicine, and did some research work on the coagulation of albumen. On leaving Edinburgh he studied at Vienna, Prague, and Paris, and in 1891 joined the Army Medical Staff, as it then was. He saw service on the West Coast of Africa, taking part in the expedition against the Sofas, for which he obtained the medal and clasp. He was able to keep up his research work, and in 1897 contributed a paper to the Medico-Chirurgical Society of London on the parasite of malaria. Later he served in Gibraltar, India, and Burma. He was gazetted Major in 1903 and retired from the Service in 1909, when he was appointed in charge of the Military Hospital, Lincoln. On the outbreak of the war his hospital was enlarged to accommodate B.E.F. patients, giving him the opportunity of thoroughly testing the ichthyol and glycerine treatment of gunshot wounds, which he advocated in a number of articles in various medical papers. He was mentioned in despatches in 1917. His death occurred on his return from a court-martial at Cork.

Major Duggan is described as one who was always devoted to the welfare of others, and in him the Lincoln depôt has lost a good friend. He married in 1895 Crystal, youngest daughter of the late W. H. Maunde, of Worcester, and leaves three children.

BENJAMIN HILTON LEIGH, L.R.C.P. EDIN.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain B. H. Leigh, who died on Oct. 9th, at the age of 51 years, from an illness contracted on foreign service, was eldest son of the late H. H. Leigh, of Piura, Peru. He came to this country at the age of 12 and was educated at Prior Park College, Bath. Later he entered the School of Medicine at Owens College, Manchester, taking the triple qualification at Edinburgh in 1896. For some years he was in practice at Southend-on-Sea, until in April, 1915, he obtained a commission in the Royal Army Medical Corps. He went overseas in the following August, first to Malta and afterwards to Salonika, being invalided back to this country last April. His death occurred in the Manor War Hospital at Epsom.

Captain HARRY DUNLOP, C.A.M.C., who died of wounds on Nov. 2nd at the age of 35 years, was born at Kingston, Ontario. He graduated in medicine at Queen's University, Kingston, came to England in September, 1916, and served as M.O. in units in England until November, 1917, when he went to France with the 102nd Battalion. He was attached to this unit when he received the wounds of which he died.

Captain NEVILLE HALL LITTLE, C.A.M.C., who died of wounds on Oct. 29th at the age of 25 years, was a native of Trenton, Ontario, and graduated in medicine at the University of Toronto in 1916. He came to England in April, 1917, was sent to France in July, 1918, and served for three months with a general hospital and later with a field ambulance.

Captain CHARLES HENRY VERNON SMITH, C.A.M.C., who died on Nov. 1st at the age of 22 years, was a native of Oxford, Ontario, and graduated in medicine at McGill University in 1914. He came to England in March, 1916, and went to France in July to serve with a general hospital and afterwards as regimental M.O. until he was invalided to England.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Capt. G. L. Maule, R.A.M.C., died at Bagdad of pneumonia, only son of the late Dr. W. Maule, of Birkdale, Lancs.

Second Lieut. A. Irving, Sikhs, killed in action in Mesopotamia, youngest son of Dr. M. H. C. Irving, of the British Guiana Medical Service.

Second Lieut. R. R. O'Conor, Coldstream Guards, died in England of pneumonia, younger son of Dr. J. O'Conor, of the British Hospital, Buenos Aires.

Surg. Lieut. W. H. Pickup, R.N., died in England of pneumonia following influenza, second son of Dr. W. J. Pickup, of Coventry.

Capt. L. F. H. Beach, D.S.O., Queen's Regiment, died of broncho-pneumonia, son of Dr. F. Beach, of Coulsdon, Surrey.

Lieut. A. J. T. Eccles, M.C., R.E., died of influenza, third son of Dr. G. T. Eccles, of Hove, Brighton.

MENTIONED IN DESPATCHES.

In a despatch, dated August 20th, 1918, received from the Commander-in-Chief in India, the following reference is made to the medical services:—

The sick and wounded despatched to India from oversea theatres of war, as well as those invalided from Waziristan and other theatres of frontier operations, have been adequately and sympathetically cared for. A number of war hospitals have been formed, other hospitals have been expanded and improved, and ruling chiefs and others have generously provided hospitals and convalescent homes in Bombay and elsewhere, in which everything possible has been done for the comfort of the sick and wounded. The satisfactory health of the troops, both in the field and in India, affords striking testimony as to the value and efficacy of these measures and the skill, forethought, and administrative capacity of the medical services.

Amongst the list of mentions in connexion with the despatch are the names of the following medical officers:—

Lt.-Col. J. M. Crawford, O.B.E., I.M.S.; Maj. G. I. Davys, I.M.S.; Maj. H. Hallilay, I.M.S.; Lt.-Col. T. Jackson, I.M.S.; Col. W. E. Jennings, I.M.S.; Maj. J. C. Kennedy, R.A.M.C.; Lt.-Col. W. G. Liston, C.I.E., I.M.S.; Col. W. Molesworth, C.I.E., I.M.S.; Maj. G. F. Rugg, R.A.M.C.; Col. A. W. Sheen, R.A.M.C (T.F.); Maj. A. E. Walter, I.M.S.; Lt.-Col. C. F. Wanhill, R.A.M.C.; Lt.-Col. J. W. Watson, I.M.S.

FOREIGN DECORATIONS.

French.

Croix de Guerre.—Capt. (acting Maj.) R. P. Ballard, M.C., R.A.M.C., Spec. Res.; Temp. Capt. (acting Maj.) P. Carney, M.C., R.A.M.C.; Capt. (acting Maj.) D. Dougal, M.C., R.A.M.C., Spec. Res.; Temp. Capt. (acting Maj.) J. A. Doull, R.A.M.C.; Lt.-Col. (temp. Col) F. G. Fitzgerald, D.S.O., R.A.M.C.; Lt. W. A. Fraser, R.A.M.C., Spec. Res.; Temp. Capt. L. Gameson, R.A.M.C.; Temp. Capt. J. F. McLay, R.A.M.C.; Temp. Capt. S. A. W. Munro, R.A.M.C.; Capt. (acting Lt.-Col.) E. Percival, D.S.O., M.C., R.A.M.C.; Temp. Capt. D. J. Stokes, R.A.M.C.; Temp. Capt. (acting Lt.-Col.) R. Svensson, M.C., R.A.M.C.; Capt. (acting Lt.-Col.) F. Worthington, D.S.O., R.A.M.C.; Maj. (temp. Lt.-Col.) H. A. Davidson, D.S.O., R.A.M.C.; Maj.-Gen. J. B. Wilson, C.B., C.M.G., A.M.S.

Belgian.

Ordre de Léopold.—Chevalier: Capt. A. R. Cook, Uganda M.S.
Ordre de la Couronne.—Officier: Capt. E. L. Fyffe, R.A.M.C.

Italian.

Order of the Crown of Italy.—Officer: Lt.-Col. (acting Col.) H. Hewetson, D.S.O., R.A.M.C. Cavalier: Temp. Capt. J. H. Peek, R.A.M.C.
Croce di Guerra.—Temp. Capt. A. F. Readdie, R.A.M.C.
Bronze Medal for Military Valour.—Capt. (acting Maj.) A. E. P. McConnell, M.C., R.A.M.C. (T.F.).

Egyptian.

Order of the Nile.—2nd Class: Surg.-Gen. Sir J. Maher, K.C.M.G., C.B. 3rd Class: Lt.-Col. H. W. Thomson, R.A.M.C.

Portuguese.

Red Cross Medal.—2nd Class: Maj. (temp. Lt.-Col.) H. G. Pinches, R.A.M.C.

Japanese.

Order of the Sacred Treasure.—2nd Class: Surg. Rear-Adml. P. B. Handyside, C.B.

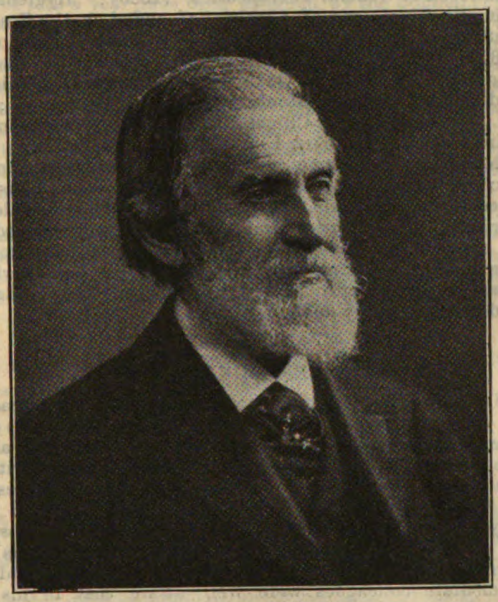
Obituary.

SIR HERMANN WEBER, M.D. BONN, F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE GERMAN HOSPITAL, LONDON, AND TO THE ROYAL NATIONAL CONSUMPTION HOSPITAL, VENTNOR.

As we have already announced, Sir Hermann Weber, who may be regarded as the founder of the science of climatotherapy, died at his residence, 10, Grosvenor-street, at the advanced age of 95, on Nov. 11th. Born of a German father and an Italian mother, his sympathies were entirely on the side of England, his adopted country, where he worked for 75 years; his younger son, Lieutenant-Colonel Weber, D.S.O., R.F.A., and all his grandsons of military age, five in number, have fought in the war, and one of these laid down his life at Ypres at the beginning of hostilities.

Hermann Weber commenced his medical studies at Marburg, whence he proceeded to Bonn, where he graduated M.D. in 1848. In his student days at Marburg he met Carlyle; while his knowledge of the works of Shakespere and his determination to read them in the original brought him into social relations with English visitors at Bonn, among them being Sir James Simpson. A strong feeling in favour of British sociology was thus created, and Weber applied for and obtained the post of house physician to the German Hospital at Dalston. The many friends that he made there, the acquisition of a private practice, membership of the now



SIR HERMANN WEBER.

defunct Society for Clinical Observation, to which much medical progress was owing at the time, and finally the marrying of an English wife in 1854 were all factors in the decision to make England his home. He accordingly entered as a student at Guy's Hospital in order to obtain an English qualification, and in 1855 became a Member of the Royal College of Physicians of London and shortly afterwards a Fellow of that body.

All idea of returning to Germany now disappeared from his mind, and from a small clientèle of mostly foreign patients Weber's practice soon extended into English circles. His advocacy of the high valleys of the Engadine as health resorts in many conditions of debility added to his reputation, and the return from those climates of distinguished patients in renewed vigour proved the correctness of his judgment. Himself an ardent mountain climber—in his eightieth year he traversed the Diavolezza—and knowing the Alps thoroughly, his selection of spots where graded exercise could be combined with quiet and beautiful environment was unerring. Among famous men whose improvement in health under Weber's care gave public advertisement to the claims of climatotherapy may be mentioned

five Prime Ministers—namely, the Lord Derby, Earl Russell (Lord John Russell), Lord Salisbury, Lord Rosebery, and Sir H. Campbell-Bannerman—and he was frequently consulted on the choice of a health resort for members of the Royal Family. His professional status was recognised by the Royal College of Physicians, where he served on the Council for five years, being Censor in 1879 and 1880. In 1899 he received the honour of knighthood. Weber's long and distinguished association with life assurance work formed another claim to public recognition. He was medical officer to the central office of the North British and Mercantile Insurance Company for many years, was President of the Life Assurance Medical Officers' Association from 1897 to 1899 inclusive, and his presidential address on Heredity in Relation to Life Assurance showed considerable prevision in respect of matters that have since become subjects for more elaborate discussion and arrangement.

Sir Hermann Weber actually retired from practice at the age of 80, but for the 15 years which remained to him he continued to take the keenest interest in his profession. He contributed to medical periodicals and wrote a work on "Means for the Prolongation of Life," the fourth edition of which was reviewed in these columns recently. The value of his teaching here was certainly well illustrated in his own case, for at the age of 95 he was able to walk on an average 50 miles a week regardless of weather. Of his other literary work the following may be mentioned in illustration of the duration of his activities: "Notes on the Climate of the Swiss Alps" (1864); Klimato-Therapie in "Ziemmsen's Handbook of General Therapeutics" (1880); "Hygienic and Climatic Treatment of Phthisis" (founded on the Croonian lectures of the Royal College of Physicians of London for 1885); "Treatment of Phthisis by Residence in Elevated Regions"; articles in Quain's "Dictionary of Medicine" and Allbutt and Rolleston's "System of Medicine"; with Dr. Parkes Weber "Climatotherapy and Balneotherapy," third edition, 1907 (THE LANCET, Feb. 16th, 1907).

Numismatics became his hobby in later years, and he became an accepted authority on Greek coins. Visits to Greece, Sicily, Tunis, Egypt, Asia Minor, and Palestine enriched his collection and at the same time helped him to confirm his view and gather further information on climatology. During the last weeks he had obviously been losing strength rapidly, as he himself knew. But the end came suddenly and peacefully.

JOHN BIERNACKI, M.D. GLASG.

Dr. John Biernacki, who died on Oct. 11th, was a graduate of the University of Glasgow (M.B. 1889, M.D. 1898) and a licentiate of the three Scottish Colleges. Throughout almost the whole of his professional life he was concerned with the study and treatment of the ordinary infectious diseases, and at the date of his death he had been for some 23 years physician-superintendent of the Plaistow Fever Hospital. In the district served by the hospital his name has long commanded public confidence and gratitude, and his immediate colleagues were well aware that in his own department of practice he spoke as a clinical authority of the first order. Had he lived, a wider teaching would probably have been open to him, for he had accumulated many case-records and studies, and he always intended to found on these a systematic exposition of his experiences and conclusions. Something in this direction he did, indeed, accomplish, as may be seen in a lucid chapter on "The Infective Diseases of Temperate Climes" in Dr. Bain's "Text-book of Medical Practice." But he had much more to say and he waited for a quieter day in which to say it. Leisure, however, came to him in scanty supply, and he was ever restrained by a disinclination to publish any writing until by repeated review and self-criticism he had at least approached his own somewhat austere standard of worthiness. The artist in some measure hindered the teacher, and medicine is the poorer for the restriction. In his clinical and organising work Biernacki was severely practical, thorough, and business-like—a careful and exact observer and a thoughtful and painstaking student. That in addition he was possessed by wide intellectual and artistic interests was hardly known save to a few intimate friends, for his natural habit of silence and reserve hid not only the range of his thought but also the original quality of his mind and his capacity for tenderness and emotion. It was only in the intimacy of close and affectionate comradeship that these qualities came to the surface and the full measure of the man was known and appreciated. In such a circle his name has an abiding place as a companion whose thought touched all problems and as a friend ever ready for loyal and generous service. Here certainly he has left memories which enrich and strengthen life. C. O. H.

ALFRED ELLINGTON STANSFELD, M.D. CAMB., F.R.C.P. LOND.,

PHYSICIAN, METROPOLITAN HOSPITAL; SENIOR DEMONSTRATOR OF PATHOLOGY, ST. BARTHOLOMEW'S HOSPITAL.

MEDICINE has suffered a great loss by the early death, on Nov. 25th, from influenzal pneumonia, of Dr. A. E. Stansfeld.

Alfred Ellington Stansfeld was born in Stoke Newington on Dec. 11th, 1882, educated at the Central Foundation School, Cambridge, and held a scholarship at St. John's College from 1902–7. He took a first class in Part II. (Physiology) of the tripos, and going on to St. Bartholomew's Hospital, London, obtained an entrance scholarship and most of the other distinctions there available in medicine. He took the M.B. Camb., and became M.R.C.P. in 1911, the M.D. Camb. following in 1915. After holding resident posts at St. Bartholomew's he became casualty physician and then assistant demonstrator of pathology, as well as physician to the Metropolitan Hospital. His election to the F.R.C.P. occurred this year.

Stansfeld possessed not merely a high degree of intellectual ability, but close powers of observation and an unlimited capacity for hard work—a combination which was already

DR. A. E. STANSFELD.

beginning to bring him considerable success in clinical medicine. Added to this, he was an excellent and popular teacher, always ready to put aside his own work in order to help a student over some difficult point. He was, moreover, a good organiser, and more than one hospital had to thank his ingenuity and tact for arrangements enabling work to be carried on during the war. Although his own bent was clinical medicine, he had devoted much of his attention during the past six or seven years to pathology, occupying the post of demonstrator in this subject at St. Bartholomew's Hospital. Only the trying duties of routine work prevented him from following out researches on anaphylaxis and kindred subjects which he had commenced with every prospect of success. The apparatus which he had devised for the transfusion of blood[1] proved remarkably useful, and his services in this direction were much in request. At the outbreak of the war he was by no means averse from military service, but yielded to the representations that some few must remain to carry on the work and teaching of the hospital. This duty he faithfully carried out, and the services he thus rendered

[1] THE LANCET, 1918, i., 334.

were truly as valuable as any he could have offered by taking a commission. Two hospitals claimed his time, St. Bartholomew's and the Metropolitan, and to both he devoted unstinted time and labour, undertaking a part of the military work at the Metropolitan in addition to his ordinary routine.

Stansfeld was a robust man, but such toil as he underwent during the war cannot have been without effect upon the strongest constitution, and probably played a part in the issue of his fatal illness. His loss will be deplored not only by the institutions with which he was connected but by a wide circle of friends and colleagues. His loyalty as a colleague and his devotion as a friend were conspicuous features in his character. The thronged memorial service at St. Bartholomew's on Nov. 28th was a testimony to the genuine regard and affection in which he was held.—F. W. A.

THE Rev. DANIEL MCNEILL, M.D., of Orkney, whose death occurred on Oct. 15th at the age of 78, was born at Drumlemble, Argyllshire. Educated at the University of Glasgow, he combined the studies of medicine and theology, with a view to entering the foreign mission field; but on a chance visit to the Orkneys he decided, at the earnest request of the people, to settle on these remote islands, where for half a century he devoted himself to the care of the bodies and souls of his community. Since the war he had been living in nominal retirement in Edinburgh, but had been doing as much medical and clerical work as his years allowed. He died literally "in harness." Dr. McNeill was a man of many gifts—too versatile, indeed, to make a notable success in any one line; but his life was as useful as it was full and varied. His abounding sympathy, his kindliness, and his humour endeared him to the people to whom his life was dedicated. Of his family of six sons and six daughters, four sons and three daughters are graduates or alumni of Glasgow University. Two sons gave their lives in the war; one is in Palestine; another, Captain D. Dewar McNeill, R.A.M.C. (T.), is serving in France; and a daughter, Dr. Mary McNeill, is with the Scottish Women's Hospital at Salonika.

Medical News.

BRITISH MUSEUM (NATURAL HISTORY): SWINEY LECTURES.—A course of 12 illustrated lectures on Man and His Ancestry is being delivered by Dr. Thomas J. Jehu in the lecture theatre of the Royal Society of Arts during December and January, at 5.30 P.M., beginning Dec. 10th. Details are given in the Diary. Admission is free.

THE BELL FUND.—Dr. S. A. Kinnier Wilson asks us to acknowledge a donation of £3 3s. to the Dr. J. H. Bell Fund from Temporary Surgeon Paul C. Gibson, R.N. Subscriptions should be sent to Dr. Wilson, at 14, Harley-street, London, W. 1.

INFLUENZA IN BELFAST.—The influenza epidemic still prevails in Belfast and surrounding districts, perhaps to a less degree among the better classes; but, on the other hand, it has extended widely among the poor, though even among them older people seem to be less prone to attack. The mortality for the week ending Nov. 23rd was, in Belfast, 65 per 1000, and of the deaths which occurred over 250 were due to influenza. The epidemic has demonstrated three things—the absence of any known reliable treatment, specific or preventive; the hopeless failure of public health measures to have the least effect in combating the spread of the disease; and the want of any central organising authority (such as the Local Government Board in Dublin or local bodies) to deal with a confessedly difficult problem. The latest measure to be adopted by the Public Health Committee of the city of Belfast on Nov. 28th was to issue an Order by which the primary schools are (owing to the continuance of the influenza epidemic) to be kept closed until a date to be fixed by the committee after the Christmas holidays, a measure which will only tend to drive the young people affected into the kinemas, which are not closed. At one of the Parliamentary election meetings—for the Ormeau division—a speaker roundly blamed the city council for their action in closing Sunday schools and in leaving the kinemas open. It is only fair to say that the public health authorities of Belfast have no power to close places of amusement, and that the medical officer of health has been instructed by the Health Committee to communicate immediately with the Local Government Board with reference to obtaining compulsory powers to close such places of public entertainment. Reports from the various districts of Ulster show that so far there is very little abatement in the influenza epidemic.

Correspondence.

"Audi alteram partem."

EPSOM COLLEGE.

To the Editor of THE LANCET.

SIR,—It is again my duty, as treasurer of Epsom College, to make an earnest appeal for new subscriptions, in order that the Council may be able to maintain undiminished the work of the Royal Medical Foundation attached to the College.

As your readers will recollect, this work consists of two branches—viz., pensions of £30 a year are given to 50 aged and impecunious medical men or their widows, and an education of the highest class at Epsom College is provided for 50 necessitous sons of medical men, who also receive gratuitously maintenance, clothing, and pocket money.

In consequence of the numerous calls in connexion with the war, in addition to the increase of taxation and the general rise in prices, many annual subscriptions have been withdrawn, whilst others have been reduced in amount.

Applications for assistance are being received as a direct consequence of the war, and already the Governors have elected as Foundation Scholars (1) the son of a medical officer who was killed in action on the *Good Hope* in 1914; and (2) the son of another medical officer who was killed in action in 1917. Furthermore, Salomons Entrance Scholarships of £50 a year have been awarded by the Council (1) to the son of a medical officer who was killed when the *Royal Edward* was torpedoed in 1915; and (2) to the son of another medical officer who lost his life when the *Arcadian* was torpedoed in 1917.

I earnestly appeal to those of your readers who already support the Foundation to increase their contributions, at least for a few years, if possible, and I urge upon those who do not at present subscribe annually to do so. To the latter I wish especially to make this request at a time when so many members of our profession, their widows, or their orphans, are in need, and I beg of them to be so good as to respond sympathetically to this appeal at once. A sum of not less than £4500 must be procured in annual contributions if the numbers of beneficiaries are to be maintained.

I am, Sir, yours faithfully,

HENRY MORRIS,
Honorary Treasurer of Epsom College and its Royal Medical Foundation.

Office: 37, Soho-square, London, W., Nov. 29th, 1918.

A NATIONAL TRIBUTE TO VOLUNTARY AMBULANCE WORKERS.

To the Editor of THE LANCET.

SIR,—In your annotation on "first-aid in ordinary life" (Nov. 30th) you rightly emphasise the importance of the kind of work which is being done by the College of Ambulance. It is impossible to say how far the advent of peace may cripple this work by reducing the attendance at the classes, but the firm intention of the council is to continue the teaching carried on there; it is hoped in coöperation with the important bodies whose function is the practical application of first-aid in peace and war.

There has been a great demand for the instruction which the college supplies during the war, and it has therefore been almost self-supporting, but this cannot be expected to continue. The council are, therefore, appealing to the public for funds in order that the college may have an assured income at least sufficient to ensure adequate remuneration for its teaching and official staff. It may be hoped that in gratitude for what has been done and in its own interest the public will respond generously.

I am, Sir, yours faithfully,

RICKMAN J. GODLEE,
President of the College of Ambulance.

Wimpole-street, W., Dec. 3rd, 1918.

To the Editor of THE LANCET.

SIR,—The magnificent work accomplished during the war by the voluntary ambulance workers in the field, along the lines of communications, and at the base, at sea, on railways, and in hospitals at home stands out as one of the most prominent features of national accomplishment during

the past four years. Men and women have alike contributed; they have each in their own spheres filled the great gap in the war machine. They began to organise and to train for their special work before the war, for as long ago as 1908 the first V.A.D. was formed in London, so that when war was declared there was no difficulty in extending the work upon this well-founded basis.

After undergoing training for their duties they came forward in their tens of thousands to offer their services. No task was too hard, no duty too menial, no risk too great for these men and women to undertake. By day and night, in the stations and hospital wards, in the scullery, on all fronts, from France to Mesopotamia, these voluntary workers have brought credit and lasting fame to their country and themselves. Soldiers and civilians would combine in showing their appreciation were the means of doing so brought before them. How better can that be done than by establishing centres throughout the country where the work to which they have devoted themselves can be continued and perfected? Ambulance is for peace-time as well as for war.

War duty is but an ephemeral portion of ambulance work; civil ambulance is for all time. Modern military ambulance was organised in Germany, but civil ambulance was first instituted in Britain, and its performance entrusted to the public to accomplish. It is not taught in our medical schools; it cannot be satisfactorily taught except in schools technically equipped for this purpose. The College of Ambulance, founded in 1914, is the only school of the kind in the Kingdom; it is a model for other centres to go by.

Since 1914 25,000 people have been trained there, and the college has established its usefulness and proved that the public appreciate its teaching. For the sake of the public good, and as a tribute to the men and women who have given their time, and in many cases their lives, for the cause of ambulance, let us consecrate a building and perpetuate the work they have at heart and where ambulance can be taught worthy of the great cause. The college gives technical training, open to all teachers and students of the ambulance societies of the nation.

I am, Sir, yours faithfully,

JAMES CANTLIE.

College of Ambulance, 3, Vere-street, London, W.1,
Dec. 2nd, 1918.

TREATMENT OF INFLUENZA.

To the Editor of THE LANCET.

SIR,—In the face of so kindly a reference to my article upon this subject in your issue of Nov. 23rd, it seems ungracious to point out that Dr. C. W. Vining (THE LANCET, Nov. 30th) has read the letter of my contribution rather than its spirit. And in one particular he has misread the letter, I fear with malice aforethought, since I mentioned the "turtle soup" to condemn, and not to advise, it! The spirit of my article surely was that certain simple principles should be followed, by the doctor and nurse if available, and if not, then by the friends under the doctor's instructions. Even "the harassed doctor" can open windows, draw back curtains, point out the reason for disallowing the pile of stuffy bedclothes under which the patient is being stewed, encourage sponging, and direct generally those who, though eager to be taught how to help, too often, like Milton's hungry sheep, "look up and are not fed." These were the things I chiefly dwelt upon, urging that they were more important than the details which Dr. Vining has extracted for the purpose of his letter. Dr. Vining says my paper "would have been more helpful if he could have formulated a workable scheme for the handling of the many serious cases amongst the poorer classes." This was obviously not my thesis. I entirely endorse Dr. Vining's opinion that the civilian population has suffered severely because of the "apparent helplessness of the public health, Poor-law, and hospital authorities." The want of organisation, and of some central control, are, as Dr. Vining points out, pathetically evident. And the patience of the British public is once more a thing to wonder at, though not to admire.

I am, Sir, yours faithfully,

London, Dec. 2nd, 1918. THOMAS HORDER.

Dr. C. MUTHU writes of four cases of influenzal pneumonia successfully treated with liquid paraffin as recommended by Dr. A. White Robertson. In all four cases the temperature went up suddenly, there were headache, flushing of the cheeks, double pneumonia with pleurisy, acute congestion of the bases, with temperature ranging from 103° to 105° F. In addition to general measures the bowels were kept freely open by aperients and by liquid paraffin. Over the chest, front and back, was applied a lint jacket soaked in paraffin oil (yellow), covered over with a double layer of jaconet, the dressing being renewed every 24 hours. When the temperature had fallen to 99° the oil dressing was removed, the bases were painted with liniment of iodine and thermogene wool was applied over the part. All the patients recovered and convalescence was uninterrupted.

Dr. H. O. BUTLER (Chiswick) writes of 500 consecutive cases of influenza, with 1 death, all treated—after an initial purge of castor oil or calomel—with 20–30 gr. of bicarbonate of soda by the mouth four-hourly, and tepid sponging if the body temperature rose above 103° F. The soda relieves abdominal pain and distension, and acts, Dr. Butler thinks, by inhibiting the growth of the causal organism and neutralising its toxin. Cases were not considered to be influenza unless they showed catarrhal signs in the lungs. The fatal case of the series had persistent vomiting of blood and mucus, so that the soda was not retained.—Dr. R. C. LEANING (acting M.O.H. for Chiswick U.D.) adds a note confirming the superiority of this method of treatment over others in use, also attributing its success to the neutralisation of intestinal toxins.

Dr. A. J. EAGLETON and Mr. H. H. BUTCHER write to make a suggestion for treatment of the pulmonary and septicæmic complications of influenza based on their experience at the Military Hospital, Sutton Veny, Wilts. Their routine is a rapid examination of the sputum to determine (if possible) if the *Streptococcus longus* or the pneumococcus is the chief factor of the secondary infection. Streptococcal or pneumococcal serum is then given combined with complement. The pneumococcal serum was prepared after the method of P. Kyes by inoculating fowls intravenously and subcutaneously with proved virulent cocci obtained from autopsies. The complement used was not more than 48 hours old, and was obtained by needling guinea-pigs' heart, separating the serum from the blood so obtained, and diluting it with 3 parts of carbolised saline. 4–5 c cm. of serum and the same amount of complement are mixed in the syringe and injected into the subcutaneous tissue of the abdomen. Beneficial effects were produced in many cases.

Dr. W. C. MINCHIN (Herstmonceux, Sussex) writes to say that he has treated many patients with tri-methenal allylic carbide and that he can endorse the results recorded by Mr. W. Allingham in THE LANCET of Nov. 9th. Five patients constantly using preparations of allyl for other ailments, and residing in different houses in which the inmates were all stricken down with influenza, have themselves remained immune.

THE SPACING OF INJECTIONS IN THE MAINTENANCE OF A PNEUMOTHORAX.

To the Editor of THE LANCET.

SIR,—The very needful warning which Dr. Claude Lillingston has sounded in your issue of Nov. 30th, under the above heading, as to the risk of re-expansion and adhesion of a collapsed lung when too long an interval between "fillings" is allowed to elapse, tempts me to support his case with a parallel illustration, and also, if I may, to extend his danger area so as to cover a closely allied pitfall which awaits the feet of the unwary. And first of all for the illustration.

Towards the end of 1916 a lady was brought to me by a sanatorium physician for advice as to the continuation or otherwise of pneumothorax treatment. The collapse had been initiated some 12 months previously at another sanatorium; six months later a pleural effusion appeared, and the fillings had been abandoned for some months owing to the occurrence of troublesome "reactions." At the time I saw her all trace of gas had disappeared; there was fluid up to the second rib covering expanded lung, which supplied loud blowing breath sounds and abundant crepitations, and appeared to be adherent at the apex. I strongly advised re-establishment of the pneumothorax, and myself replaced the fluid with gas, and fortunately succeeded in separating off the adhering apex. She returned to the sanatorium and began to improve on monthly fillings, and continued to do so at another sanatorium to which she subsequently moved. But here, unfortunately, an interval of two months was allowed to elapse between two fillings, and she returned to me in May, 1917, with the lung again partly expanded and

adherent over the lower half of the chest wall behind. Fortunately the expanded lung tissue appeared to be of passably good quality, so no attempt to separate it off was made, nor if it had been would it in all probability have proved successful.

Here, then, we have a two-fold example of the danger to which Dr. Lillingston draws attention, and also, incidentally, of the disadvantage to pneumothorax cases of wandering from place to place, so that they lose touch with those who were acquainted with their lung before its collapse, and therewith the benefit of a consistent line of treatment.

The further pitfall to which I desire to direct attention is the danger of such re-expansion and adhesion of the lung resulting from failure to readjust the intrapleural pressure in pneumothoraxes of long standing. It was my misfortune to experience several such happenings before I fully realised the tendency of pneumothorax cavities to contract with time, even in cases where no pleural inflammation had ever been observed. This contraction has generally been referred to in the literature as if it were of occasional occurrence only, but in my experience it is the common event in cases of over a year's duration. As its result the mediastinum begins to move back towards the pneumothorax side, and a pressure which had sufficed to keep the lung collapsed through the accustomed interval now fails to accomplish this purpose. Under these conditions, unless the pressure is promptly raised, with or without a shortening of the interval, an expanded and adherent lung area will soon make its appearance, and its subsequent separation and re-collapse be difficult or impossible to accomplish. The following case will suffice to illustrate this accident.

R. W. with a left pneumothorax kept at a low pressure (0 + 4) because of a tendency to "ballooning" of the pleura. After a year of fillings at monthly intervals the lung began to show a tendency to expansion, and in spite of a slight raising of the pressure (to + 2 + 7) lung and heart became adherent to the axillary chest wall. The pressure was raised to + 6 + 11, and afterwards to + 14 + 17, with result that the heart was replaced, but a pulmonary adhesion remained without, however, any apparent detriment to subsequent treatment. There were never any evidences of pleurisy during the course of this case.

During the later stages of treatment, then, constant watch must be kept for evidences of contraction of the pneumothorax cavity, and if this occurs the pressure must be immediately raised or the interval decidedly shortened. Such cavities with fibrosed walls will bear gas pressures of + 20 cm. of water, or even of + 25 to + 30 cm. in selected cases, without any danger or discomfort to the patient. The actual pressure quickly falls, but the increased volume of gas removes the need for a shortening of the interval between the fillings. It would be interesting to learn Dr. Lillingston's experience of expansion of the lung in these later stages of prolonged pneumothorax treatment.

I am, Sir, yours faithfully,

Queen Anne-street, W., Nov. 30th, 1918. CLIVE RIVIERE.

THE ELSIE INGLIS CHAIR OF MEDICINE.

To the Editor of THE LANCET.

SIR,—Before many days have passed the Serbian Government will return from its exile in Corfu.

The committee of the Elsie Inglis London Memorial Fund hopes to hand over the money raised for the endowment of a Chair of Medicine in the University of Belgrade on the day of the entry of the Government into the capital. The required sum of £12,000 is not yet complete, and the honorary treasurers appeal to donors to send their contributions quickly.

The buildings of the University of Belgrade were shattered by the first Austrian shells of the war. The Elsie Inglis Chair of Medicine will be the first gift from this country towards the reconstitution of the national university. In Serbia, as here, "Education" is the watchword of the hour.

Yours faithfully,

MAUD SELBORNE,
TERESA GOSSE,
Honorary Treasurers of the Fund.

London Units of Scottish Women's Hospitals (London Society N.U.W.S.), 66, Victoria-street, S.W. 1, Dec. 2nd, 1918.

CENTENARIANS.—The deaths of Mary Dardis and James Foley, each aged 102, and Mary Duffy, aged 100, are reported in county Westmeath from influenza.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

—o—

TUESDAY, NOV. 26TH.

THE address delivered by the President was reported in last week's issue of THE LANCET.

Registration of Canadian Medical Qualifications.—Other Business.

The Council adopted a report of the Executive Committee in regard to the granting of medical qualifications in certain Canadian provinces. Two years ago, on information being received as to the institution of a five years' course in Saskatchewan, the acting registrar was directed to register any person who produced the licence of the College of Physicians and Surgeons of Saskatchewan and who satisfied the prescribed conditions. The Committee now reported that the question had arisen as to the position of practitioners who obtained the qualification of Member of the College of Physicians and Surgeons of the North-West Territories before they were divided into two provinces, of which one was Saskatchewan. The nature of the examination being satisfactory, the Committee had resolved to direct the acting registrar to register in the Colonial List any person holding the licence or the Membership of the College of Physicians and Surgeons of the North-West Territories obtained after examination in medicine, surgery, and midwifery, together with the licence of the College of Physicians and Surgeons of the Province of Saskatchewan, providing he satisfied the Registrar regarding the other particulars set forth in Part II. of the Medical Act, 1886.

The Council then considered *in camera* certain applications for restoration to the Register and also the question of appointment of treasurers. On the resumption of the public sitting the President announced that the acting registrar had been instructed to restore to the Register the names of James Alexander Baird Thompson, Alexander Orford Schorn, and Edmund Lyall Haynes. He also stated that Dr. Norman Moore had accepted the office of treasurer of the Council in succession to Sir Frederick Taylor, and that Dr. Moore's place as chairman of the Business Committee would be taken by Dr. Norman Walker.

The Case of Jules Michael Ralph Flament, M.D., B.Ch. Edin.

The Council considered an application from Dr. Jules Michael Ralph Flament, of Carlisle, through his counsel, Mr. A. Neilson, K.C., for the postponement of the hearing of the charges against him which had been fixed for that session. Notice of the charges had only been received on Oct. 25th, and they were not formulated in detail until Nov. 5th; also one of the charges had afterwards been altered in a fundamental particular. Dr. Flament strongly denied the charges, and Mr. Neilson submitted that three weeks was not a sufficient time in which to prepare his defence.

Sir FREDERICK SMITH, the Attorney-General, on behalf of the Ministry of Munitions, at whose instance the charges were brought, opposed the application for postponement, but said that if, as the hearing proceeded, it became evident that the practitioner's position was prejudiced through the shortness of the time he would then consent to the postponement. The Ministry of Munitions, he said, was a disappearing body, the legal adviser in charge of the case would not be in the country at the Council's next session, and already some witnesses had arrived from considerable distances.

After deliberating *in camera*, the Council decided that the case must go forward at the date originally stated.

WEDNESDAY, NOV. 27TH.

The Case of Thos. Stoney Sharpley, M.R.C.S. Eng., L.R.C.P. Lond.

The charge in this case was as follows:—

"That, being a registered medical practitioner, you abused your position by committing adultery with Mrs. Adeline Gladys Senior, whose daughter you had attended professionally, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated July 12th, 1915, and made absolute on Jan. 24th, 1916, in the case of Senior *v.* Senior and Sharpley, in which you were the co-respondent. And that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainant was Mr. Norman Senior. Mr. Sharpley was accompanied by his counsel, Mr. Le Bas, instructed by Messrs. Snell and Co. Mr. Senior was unable to attend owing to illness.

Mr. HARPER, solicitor to the Council, read the decrees of the Divorce Court and the shorthand notes taken at that hearing.

The Council having deliberated on the case *in camera*, the parties and the public were recalled, and the PRESIDENT said: Mr. Sharpley, I have to inform you that the Council has given careful consideration to your case; it has judged you to have been guilty of infamous conduct in a professional respect, and has directed the Registrar to erase your name from the Medical Register.

The Case of Isaac Bernard Barclay, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H.

He was charged as follows:—

"That, being a registered medical practitioner, with the object of obtaining the appointment of tuberculosis officer to the Derbyshire County Council, you knowingly and falsely stated in your form of application that you had held the resident appointments of house physician, Leeds General Infirmary, and clinical assistant, Liverpool Chest Hospital. And further, with the same object, that you submitted to the Tuberculosis Committee of the said Council a printed copy of a testimonial dated August 28th, 1915, which you had knowingly falsified in a material particular—viz., by making it falsely to state that you had held the appointment of assistant resident medical officer of the Winsley Sanatorium since July 11th, 1913, whereas you had in fact held such appointment for less than one month prior to August 28th, 1915. And that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants were the Tuberculosis Committee of the Derbyshire County Council, and their case was presented by their assistant solicitor, Mr. H. W. Skinner. Mr. Barclay was accompanied by Mr. F. Greer, K.C., instructed by Messrs. Rhys, Roberts and Co.

Mr. SKINNER, opening the case, said that in March, 1917, the County Council advertised the vacancy of assistant medical officer of the sanatorium, and Mr. Barclay applied by letter on April 10th, but without mentioning testimonials. On April 19th the committee interviewed him and he was appointed to the position. Shortly afterwards Dr. Fowler, the medical superintendent of the sanatorium, offered himself for military service, and it was suggested to Mr. Barclay that he should apply for that post as temporary superintendent. He did apply on May 21st, and an application form was sent to him to be filled up. It was on the information thus given that the chief charge arose, for defendant stated he had been house physician at Leeds General Infirmary, clinical assistant at the Liverpool Chest Hospital, also assistant resident medical officer at Winsley Sanatorium. Testimonials were enclosed from Mr. Gibbs, of Charing Cross Hospital; Dr. Howells, City of London Hospital; Dr. Hellier, Dr. Owen, Dr. Clegg, and Mr. Russell. At the meeting of the Tuberculosis Committee Dr. Barwise took Mr. Barclay through his application and the testimonials by which it was accompanied. On June 13th Mr. Barclay was appointed temporary medical superintendent. Owing to the fact that, when asking for the approval of the Local Government Board of the appointment, Mr. Barclay's name could not be found in the Medical Register inquiries were made, and it transpired that defendant's real name was Bernstein, and he had changed it by deed-poll, but did not have the alteration made in the Register. This explanation was frankly accepted by the committee, but later still his further statements were regarded as so suspicious that, at the request of the committee, he attended before them. His replies were so unsatisfactory that he was dismissed the post and required to leave immediately. This he did without making any protest.

Dr. BARWISE was examined and cross-examined, and his narrative supported in the main Mr. Skinner's opening.

Mr. BARCLAY gave evidence. He said he filled the form up in a great hurry in his bedroom late at night, without due care, in order to catch the last postal clearance, he having received a telegram stating that the next day was the last on which his application was receivable. The insertion of the year 1913 instead of 1915 was an error. He had no wish to deceive, especially as he knew that any misstatement he might make would be sure to be discovered. Asked as to the original of the testimonial furnished by Dr. Howells, of which he sent what purported to be a copy, he said it could not be found, but that he had received three testimonials from that gentleman. He considered he was entitled to mention on the form the various hospitals at which he obtained permission to attend in order to improve his medical knowledge.

The Council deferred the consideration of the case until the following day.

THURSDAY, NOV. 28TH.

The Council having deliberated *in camera* on the case of Isaac Bernard Barclay, the defendant and the parties were called in, and the PRESIDENT pronounced the following finding: I have to inform you that the Council, after very careful consideration, have found that the facts alleged against you in the notice of inquiry have been proved to their satisfaction. You have therefore been guilty of what is therein stated, that, with the object of obtaining a certain appointment, you knowingly and falsely altered and misstated in your applications and in your letters facts so that they should be to your greater advantage. I need not impress upon you, further, the gravity of that finding, which amounts to a finding of repeated untruthfulness. Having regard, however, to your comparative youth, and to your obvious failure to appreciate the importance of strict truthfulness in matters relating to your profession, the Council have decided to suspend their judgment against you for one year—the judgment, namely, which would proclaim you guilty of infamous conduct and erase your name from the Register. They will require you, however, to attend here next May, and to produce at the session which will then be held evidence satisfactory to the Council as to your conduct in the interval, particularly in respect of truthfulness. And they will then require you, unless judgment is pronounced in the May session, to appear before them in November next to hear what their judgment is. They will also require you, before May next, to send in to the Registrar the names of two or three persons who know you and who are of standing and respectability, to whom the Council may refer for an opinion as to your character and conduct from this time forth.

The Council have to express their acknowledgments to the Derbyshire County Council for the clear manner in which they had performed a public duty in calling attention to this case.

The Case of Stanley Henry, M.B., Ch.B. Aberd.

The charge against this practitioner was as follows:—

"That being a registered medical practitioner while acting as locum tenens for Kenelym Cobham Edwards, of Tudor House, Sawston, Cambridge, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., and attending his patients, you were drunk, and thus incapacitated from properly carrying out your professional duties towards them. And further, on or about Oct. 20th, 1917, while drunk, and in the course of a professional visit to her, you made improper advances to one Mrs. Florence Elizabeth Gee. And in relation thereto you have been guilty of infamous conduct in a professional respect."

Dr. HENRY gave evidence in denial of all the charges, and detailed evidence having been heard from witnesses on both sides the President, after consultation with the Council *in camera*, announced that the allegations against Dr. Henry had not been proved and that the charge was dismissed.

FRIDAY, NOV. 29TH.

The Case of John Stanley Francis.

The Council considered the case of John Stanley Francis, a registered dentist, who appeared before the Council at the May session. There had been at that time three police-court convictions against him for disorderly or drunken behaviour. Further consideration of the case had been postponed until this group of sessions, and the Dental Committee now reported that no fresh notice of conviction had reached the Council, and that Mr. Francis had submitted testimonials as to his character and conduct in the interval, which were regarded as satisfactory. After deliberating *in camera* the President announced that the Council did not see fit to direct the Registrar to erase the name from the Register.

"Army Education Certificate" in General Education.

The PRESIDENT announced that the Council had passed the following resolution:—

"That the 'Army Education Certificate' in the subjects of general education, if attested by a University or other Licensing Body as sufficing for admission to its course of professional study, should be accepted for registration in the Students' Register."

The Case of Dr. J. M. R. Flament.

The charges against this practitioner were two. The first alleged that he had given an improper certificate enabling an Italian subject to avoid military service. The second alleged that he had supplied a patient, desirous of procuring her own miscarriage, with certain pills at a charge of £2.

Mr. Tindal Atkinson, K.C., appeared for the Ministry of Munitions, Mr. A. Neilson, K.C., for the defendant.

Mr. ATKINSON, in his opening statement, said Dr. Flament had been practising in Carlisle for eight or nine years. The man Coia, who figured in the case, was a dining-car chef who had a confectioner's business in Carlisle. He did not wish to serve in the Italian Army, and went to Dr. Flament to see whether he was fit. Dr. Flament gave the man a certificate to the effect that he had treated him four years ago for acute septic tonsillitis, leading to abscess formation, and that four months later he had treated him for diphtheria, which had left him subject to cardiac weakness and angina pectoris. But actually, said counsel, the man had been treated by Dr. Flament once only, and that was for the removal of tonsils; he had not had either diphtheria or angina. In consequence of his occupation Coia was not called up, and nothing further was heard of the circumstances until April, 1918, when Dr. Flament sent him a bill for three guineas, followed by a county court summons. Subsequently the man was examined by a medical board and passed Grade I., and was now serving in the Manchester Regiment. The second offence alleged was that a girl named Maggie Stalker, who was three months pregnant, was anxious that her parents should not know of her condition, and, with her sister, she called on Dr. Flament in October, 1917, to ascertain whether he could give her anything "to get rid of it." The doctor examined her and offered to supply her with some pills which, he said, would cost her £2. The girls said they could not afford that sum, whereupon he wrote out a prescription. This medicine, however, had no effect. She returned, and ultimately bought the pills, but these also were ineffectual, and the baby was born in April, 1918. Counsel did not affirm that what Dr. Flament had given her was noxious; the offence was that he allowed the girl to think that the drug would effect the purpose she desired.

Considerable legal argument ensued between counsel, Mr. Neilson contending that the case ought not to be taken because the Ministry of Munitions had not obeyed the Standing Orders of the Council, which required that the witnesses should make sworn depositions, whereas in this case there had been no statutory declarations. A further reason was that the second charge was a criminal charge, and that it should first be investigated by a criminal court before this Council had any jurisdiction.

After consideration of the points raised *in camera* the President announced that the decision was to over-rule both objections and to proceed with the case. They decided to take the second charge first.

Dr. FLAMENT, MAGGIE STALKER, and other witnesses having given evidence, the Council deliberated *in camera*. The President later announced that the Council found that the facts alleged in that part of the notice of inquiry had been proved to the satisfaction of the Council.

Mr. ATKINSON said his feeling was not to proceed with the other charge.

The Council then again retired, and later it was announced that Dr. Flament had been guilty of infamous conduct in a professional respect, and the Registrar had been instructed to erase his name from the Register.

The Council adjourned on Saturday, Nov. 30th.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lieut.-Comdr. C. D. Bell to be placed on Retired List.

Surgeon Lieutenant-Commanders to be Surgeon Commanders: M. J. Laffan, A. D. Spalding, A. McCloy, F. E. Anley, A. C. W. Newport, A. Davidson, G. D. Bateman, D. P. Chapman, R. F. MacMahon, W. N. Blatchford, G. C. Cross.

ROYAL NAVAL VOLUNTEER RESERVE.

J. Sharpe to be temporary Surgeon Lieutenant.

ARMY MEDICAL SERVICE.

Col. H. M. Adamson is placed on retired pay.

ROYAL ARMY MEDICAL CORPS.

Temp. Capt. A. G. Stewart to be acting Lieutenant-Colonel whilst specially employed.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

FOOD, HEALTH, AND THE GENERAL ELECTION.

THE management of our food supplies, including their constitution and distribution, played an all-important part in the successful prosecution of the war; the subject touches all departments of life, and will be equally important in the days of reconstruction. With the advent of a new Parliament it is, therefore, reasonable that the attitude of prospective candidates towards the problems involved should be known, and with this object the National Food Reform Association, Danes Inn House, Strand, London, W.C., is putting a series of questions to all candidates for Parliamentary honours with regard to milk-supply, food adulteration, public kitchens, slaughter-houses, meals for children, the feeding of the Navy and Army, and other matters which have a direct bearing upon avoidable disease, preventive degeneracy, and upon the health of the people generally. Similar action was taken by the association during the elections of 1910, when on each occasion more than 100 candidates answered the questions in a sympathetic manner. In 1911, a meeting, convened by Dr. Christopher Addison and others, was followed by the formation of a Parliamentary Committee on Food and Health, whose activities have been suspended during the war. Its opportunities for useful work are now increased, and the support of Members of Parliament in sympathy with its operations ought to produce practical results.

THE MEDICAL MAN'S INCOME-TAX.

To the Editor of THE LANCET.

SIR,—I too have made application for the deduction from taxable income for subscriptions to the Royal Society of Medicine, THE LANCET and the *Practitioner*, and like "Medical Superintendent," whose letter appeared in your issue of Nov. 16th, was told that these items were not admissible deductions. The reason, given verbally, as I understood it, was that though these items would probably be accepted in a claim made under Schedule D they were definitely ruled out by the stricter legal terminology that appears to govern Schedule E. I then argued that as these subscriptions were made for the purpose of procuring the most recent professional literature in order to enable the doctor to keep himself up to date in his knowledge, and as this was a duty imposed on the doctor by his obligation to his patients, the items were properly most "necessary expenses," and, further, that their necessity was entirely unaffected by the particular schedule. The position would appear to be quite different from that in the case of Charlton *v.* The Commissioners of Inland Revenue, in which the reverend plaintiff was claiming relief for what was practically the voluntary purchase of a large ecclesiastical reference library.

The official to whom I applied appreciated my point, but said that in his opinion the Act was against it. It would be a graceful concession were the income-tax surveyors to receive instructions from the Commissioners to make all permissible deductions apply to both schedules equally. The cash value at issue is negligible, but the principle is worth a fight.—I am, Sir, yours faithfully,

Nov. 26th, 1918. A WHOLE-TIME MEDICAL OFFICER.

To the Editor of THE LANCET.

SIR,—Referring to the letter of "Medical Superintendent" in your issue of Nov. 16th the editorial view there expressed has been confirmed by authority higher than that of a surveyor of taxes. The real test is: Are the payments wholly and exclusively laid out for the purposes of the profession? Subscriptions paid to professional associations from which benefit is (or may be) obtained are usually allowed; but this does not, of course, cover subscriptions to private clubs. The cost of illustrated papers on waiting-room tables is not objected to. The renewal of professional books and instruments is always allowed. The word "renewal," of course, covers the purchase of a new edition to replace an earlier edition of the same book. But in my opinion it goes further and covers expenditure required to keep the medical man's library abreast of new developments, just as in the case of instruments. A medical man or a lawyer is not, as regards books, in the same position as a clergyman. In the medical and legal professions books are tools.

The outstanding income-tax case of Usher's Wiltshire Breweries is referred to officially as giving the high authority of the House of Lords for the proposition that, in calculating profits for income-tax, outgoings may be deducted, though they were not necessary, if they were commercially expedient. I am, Sir, yours faithfully,

Edinburgh, Nov. 27th, 1918. JOHN BURNS.

"DR. WISE ON INFLUENZA."

UNDER the auspices of Sir Auckland Geddes, President of the Local Government Board, a kinematograph film has been prepared by Mr. Jos. Best, B.Sc., on influenza. The film, which takes about 15 minutes to show, is entitled "Dr. Wise on Influenza." The doctor on the screen lectures to the audience on the precautions to be adopted by a person suffering from influenza, in the patient's own interest, as well as the interest of those he comes in contact with. The exhortations of the doctor are emphasised by the kinematograph pictures in a popular vein, designed with the intention of leaving a marked impression on the audience. The film is prefaced by an appeal from Sir Auckland Geddes to the public to assist the health officials by adopting the precautions indicated. The Board have a certain number of copies of the film which they are prepared to lend to medical officers of health for exhibition purposes. Application for the loan of a film should be addressed to the Medical Officer of the Board. Medical officers of health might find that the proprietors of halls would be pleased to show the film if requested.

DIARIES FOR 1919.

WITH the advent of the New Year thoughts naturally turn to diaries. Before the war diaries were far more abundant and cheaper, and perhaps not valued as they would be to-day. The first we have received is a block diary for 1919 with a tear-off blank page for each day, measuring $5\frac{1}{2} \times 4\frac{1}{4}$ inches, on which as many memoranda can be written as on a postcard, for example. The front cover has a "window" which permits the date and day always to be seen as each slip is detached. Medical men desiring it should make early application to the Anglo-French Drug Co., Ltd., Gamage Building, London, E.C.1.

THE MEDICAL PROFESSION AND THE PETROL RESTRICTIONS.

To the Editor of THE LANCET.

SIR,—Now that there is some sign of the petrol restrictions being abated I think it is not inopportune to direct the attention of the medical profession to an injustice under which they have laboured for some time past. I refer to the price they are being charged for motor spirit. I am informed that No. 2 war spirit is sold at 3*s.* 8*d.* a gallon, and a rebate of the Excise duty on this brings it—the net price—to the doctors, of 3*s.* 5*d.* per gallon. The commercial traveller or managing director of a firm, who uses his car for business purposes, buys No. 2 war spirit, *duty free*, at 3*s.* 3*d.* per gallon, so that he gets it for business purposes at 2*d.* a gallon less than does the doctor. The argument is adduced that the doctor sometimes uses his car for other than business purposes. I am sure we all wish that we had the time and the opportunity to do a little "joy-riding," but it is many a long day since we were able to do so.

I really think that now the general public are to be allowed to use their cars for pleasure purposes—and it is to be hoped that the present exorbitant price of motor spirit will drop to somewhere within the range of the peace-time price—this question of the cost to the doctor of his car for professional purposes might well be reopened.

I am, Sir, yours faithfully,

Nov. 26th, 1918. G. P.

WANTED, A HOME.

To the Editor of THE LANCET.

SIR,—A young married relative wishes to be received as a paying guest in a thoroughly comfortable home, and I have thought that through the medical profession she might hear of what she wants. Our colleagues in country towns often know where such an inmate could be received with mutual pleasure. It is not a question of a doctor's family.

I am, Sir, yours faithfully,

Dec. 2nd, 1918. M.D.

HEREDITARY ABNORMALITY.

To the Editor of THE LANCET.

SIR,—In connexion with this interesting subject (see THE LANCET, Nov. 30th), may I remind your readers of the remarkable instance brought by Dr. H. Drinkwater before the Royal Society of Medicine (Pathological Section) in February, 1917? Dr. Drinkwater's patients, two brothers, each presented symmetrical and bilateral phalangeal synostosis of both hands and both feet. Both patients were in the direct line of descent from John, Earl of Shrewsbury, who fell in battle in 1453. When the Earl's body was exhumed in 1874 it was found that his lordship had suffered from the same abnormalities as his present-day representatives, although thirteen generations had intervened between them.

I am, Sir, yours faithfully,

S. D. CLIPPINGDALE.

Holland Park-avenue, W., Nov. 30th, 1918.

THE FOOD FACTOR.

AT the Royal Institute of Public Health on Nov. 27th Alderman C. Spencer, Director of National Kitchens, traced the intimate connexion between the proper nutrition of the people and their health and productivity. In any scheme for protection against injury and disease local authorities should, he said, bear in mind the true principles of national feeding. In a town of 140,000 inhabitants, for instance, there were 4000 married women going out to work in factories, with the result that their children only obtained "scrap meals." Experience showed that where children got their food from a national kitchen weight regularly increased, while those fed on scrap meals often lost weight. Household methods of cooking had been proved inefficient and wasteful, and were often inimical to the health of the cook. A national kitchen should, in the lecturer's opinion, form an essential part of any new housing scheme. At present there were 800 voluntary and national kitchens in the country, practically all of them paying concerns. The effect of good food on productivity was shown by the fact that the presence of a canteen maintained the curve of output in the factory, which previously had been apt to fall after 11 A.M.

THE PRESENT EPIDEMIC AND THE PRESSURE ON PRACTITIONERS.

IT is necessary to call the attention of the public to means for alleviating the pressure on civil practitioners and enabling them to cope successfully with the excessive work entailed by the present epidemic. Experience seems to show that the most effective means has been the exhibition in a prominent place in the doctor's surgery of a notice saying that it would be impossible to guarantee attendance on patients the same day unless messages were left before a certain hour in the morning. Experience derived from many areas has convinced the General Purposes Subcommittee of the Central Medical War Committee that press notices have done little good compared with the above method.

THE MENACE OF THE MURINÆ.

DURING the year 1917, we learn from the Medical Officer of the Local Government Board, 38,106 rats were trapped in the London Docks. 2912 were examined and 2271 found to be *Mus decumanus*, 578 *M. rattus*, and 129 *M. alexandrinus*. One each of the two former were plague infected. The latest publication of the British Museum (Natural History) trustees, No. 8 of the Economical Series, deals with *Rats and Mice as Enemies of Mankind*, and is from the pen of M. A. C. Hinton (London Natural History Museum, B. Quaritch and Dulau and Co., 1*s.*). Its appearance is timely in view of the Rat Order of the Ministry of Food. In addition to a brief account of rats and mice in this country, their habits and breeding, the pamphlet deals with their relation to food and health, and suggests measures by which they can be controlled if not exterminated. An appendix contains notes on the structure and classification of the family of Muridæ, of which the Murinæ (rats and mice) are a sub-family, with a key to the British species. References for further reading and the excellent illustrations add to the value of the handbook.

NUTRIENT MEDIA IN THE SHOP.

To the Editor of THE LANCET.

SIR,—At this time one may see at many of the large "stores" little tables ready set out with attractive-looking sweet jellies which customers and their children partake of; they are not covered over, and are usually displayed where hundreds of people pass by, otherwise, no doubt, the latter might not realise they wanted jelly. I see larger savoury jellies also set out in "dressed provisions" departments. If a report on the number and variety of influenza and other disease germs that settle to the square inch on the exposed surfaces of these jellies were published, it might give consumers pause.

I enclose the names of two "emporiums" (which doubtless are only among many) where my statement as to the exposure of these refreshments can be verified.

I am, Sir, yours faithfully,

Nov. 24th, 1918. V. A. D.

Enquirer.—No official figures are available, but we understand that 10 years ago the names of about 800 women were on the Medical Register, and that the number now is between 1500 and 2000, out of a total of nearly 44,000.

Priority.—The subcommittee of the C.M.W.C. dealing with demobilisation has suggested certain principles for the guidance of the Ministry of National Service. The medical men of the T.F. and S.R.—numbering 1500 or so—mobilised at the outbreak of the war will have priority. Matters which will be taken into account in determining early demobilisation are age, civil state, financial and other responsibilities, and the type of practice. Other things being equal, the man over 45 will have preference over the younger man, married over single, private practitioners over whole-timers.

Observations ON THE MEDICAL EXAMINATION OF AVIATION CANDIDATES.

BY G. A. SUTHERLAND, M.D. EDIN., F.R.C.P. LOND.,
LATE MEMBER OF THE SPECIAL MEDICAL BOARD, ROYAL FLYING CORPS.

INTRODUCTORY.

THE aim of the special medical examination is to select from amongst civilians, cadets, and officers those who are constitutionally fit, or who appear to be fit, for flying duties. In order to arrive at correct decisions fitness for his work is also necessary in the examiner. Unfitness on his part may lead to two undesirable results: first, candidates who are physically fit may be rejected; and, secondly, candidates who are physically unfit may be passed. There is no doubt that in the past the flying services suffered from both of these results.

It has been assumed too readily, and not by the lay public only, that it was an easy enough thing to decide as to a man's fitness for any duty. Experience in the flying service has shown that it is by no means easy to do so as regards flying work. It is impossible to estimate how many physically fit men have been rejected for the flying service. The decision depended on the examiner's skill and experience, and on the standards he had been taught or had had laid down for him. Too often these were cast-iron standards, with a fine halo of antiquity about them, but quite unsuited for present-day purposes. The employment of the same standards led to the admission of many unfit men into the flying service. These results are more serious in this service than in the case of the older services, because a flying man's training is a particularly expensive one, and when he fails or breaks down it usually means that his flying days are over for ever.

The Scope of the Examination.

There are certain things that the examiner must bear in mind. It is not the case that flying duties require special qualifications other than those called for in many branches of sport and mountaineering and in many country occupations. If, for instance, we take the public-school boy who has been captain of his football team and has held his own in the class-room we require no elaborate examination with special tests to estimate his physical fitness for flying. At the other extreme we have the civilian lad who is town-born and town-bred, whose practical experience of athletics has consisted in looking on at football matches, whose working hours have been passed in an office, and his leisure hours in the streets or a music-hall. Merely by inspection one can decide at once that he is quite unfitted for flying work. Between these two extremes there is a large intermediary class requiring careful medical examination.

The examiner should also know that the diseases and disorders of flying men are not different from those met with in the civilian population. The contrast between the two lies in this, that the causes of flying disabilities are not present in ordinary life. The results are the same in both cases. Thus air-sickness bears a very close resemblance to sea-sickness. The man who gets sea-sick when the vessel leaves port on a calm day gets very much worse when the ship is storm-tossed. The pilot who gets sick at straightforward flying gets very much worse when the plane is buffeted about by pockets of wind or when stunting is indulged in.

While it is extremely desirable that the examiner should know how the causes of flying disorders will affect the candidate before him that knowledge is not yet forthcoming. It is asking too much of the examiner at the present stage of flying to expect him to recognise the proper flying temperament or any inherent tendency to develop disabilities in the air. What he should concentrate on is the selection of those only who are physically and mentally fit. The rest is guess-work.

Special Tests.

Attempts have been made both in this country and in America to standardise the examination by means of fixed tests. Some would allow the tests, or even a single test, to dominate and decide the examination. So far, however, no tests have been found which can be accepted as reliable, and most of them require much more testing, especially by experience, before they can be accepted as definite standards.

One must remember how fallacious tests have proved in the past. A systolic murmur heard at the apex was for long considered an infallible test of heart disease and disability. Its presence has led to the rejection of countless fit men for army and navy service. It was only after long experience and bitter controversy that this test was recognised to be of no value in deciding as to the condition of a man's heart. It was useful in calling for a careful examination of the heart, of the significance of the murmur, and of the presence or absence of any associated cardiac lesion or functional disability. This is the value of all special tests, that they direct one's attention to certain organs or functions which require specially careful examination. For this purpose they are to be welcomed and used as finger-posts, but not to be regarded as impassable barriers.

Guiding Principles.

Instead of endeavouring to standardise the tests I think that an attempt might be made to standardise the examiners. If certain guiding principles were drawn up and accepted the carrying out of these principles would bring all the examiners into line. If the examiners viewed the medical problems involved from the same standpoint the results of the examination would tend to be uniform.

In the following pages certain broad principles are suggested, as the result of my experience, which may serve as a guide to the medical examiner who is beginning this work. The examiner does not start with an aptitude for assessing the fitness of a candidate for air duties. It has been my experience and that of most trained examiners I have talked to, that a somewhat long and arduous apprenticeship has been necessary before a decision can be given with confidence. That has been partly due to the fact that we had no guiding principles and that the problems set were entirely new. This period of apprenticeship will be considerably shortened if the examiners are agreed about the principles of examination and the standards to be adopted, and can convey them to those who are beginners.

It is not advisable for the examiner to bring too many preconceived ideas with him on commencing this work. He may in the course of his professional work have acquired certain views which have not been submitted to the criticism and judgment of his compeers. He may feel inclined to reject or to pass a candidate on grounds which would not commend themselves to other examiners. Such views and such decisions may usefully form a subject for discussion at the Examiners' Board, but should not be carried out in practice at an early stage of the work. On the other hand, the new examiner is perfectly justified in declining to allow his judgment to be over-ruled because of some test, with an authoritative name attached, or because of some scientific toy which is stated to be an automatic pilot-finder. He is perfectly entitled to demand some definite proof of the validity of all such tests, and some more evidence of their value than that of the name behind them, or the fact that they are said to be amongst the latest scientific discoveries.

Essential Qualifications for Air Service.

The examiner must consider what are the special duties and dangers which will be experienced in a flying career. A pilot will have to carry out his duties in a new element, or at least in one which varies much in its composition from the stable atmosphere he has been accustomed to live and work in. He will have to acquire the complete control of a car moving through space in such a way that all his controlling movements become as automatic and unconscious as those of an expert bicycle-rider. He has, further, to be prepared for active fighting in the air, the attacking of enemy air-craft, and the protection of his own aeroplane and of his own life. No small requirements these.

From the medical standpoint I consider that there are certain necessary qualifications to meet these conditions successfully, or at least with the prospect of success. The first is a good physique; then comes a sound cardio-vascular system; and, lastly, a strong and stable nervous system. These are the essential qualifications required to meet the special conditions of the air service, on the principle that where the strain falls the resisting power must be strong.

The necessity for these qualifications is not based on theoretical considerations only. Practical experience at the Invaliding Board of pupils under instruction who have failed, and of officers who have broken down from accidents, or stress of service, or inability to continue flying, has supplied strong confirmatory evidence. The symptoms complained of are numerous and various, such as fainting, giddiness, loss of consciousness, loss of control, exhaustion, headache, sleeplessness, loss of confidence, &c. An examination of those who present such symptoms and who are not suffering from active illness or gross injury shows that there has been usually an exhaustion or a giving out of the cardio-vascular or the nervous system. This is the outstanding fact in the vast majority of cases, and it is an indication to the examiner that he will do well to concentrate on these two systems in determining the fitness of a candidate for the flying service.

The examiner should bear in mind that while he has to exclude candidates with gross disease of a disqualifying kind it is not from gross disease that the flying men break down and become useless. Apart from the direct injuries or wounds of the service and the effects of previous or recent illness, it is functional disabilities which bring flying men before invaliding boards and which swell the numbers of the "permanently unfit for further flying." Some organ or some system has given out and the flying power has gone, although the officer may be perfectly fit for general service on the ground. It is this tendency to functional disability and the importance it assumes in flying work that the examiner must remember. His duty is to seek out and discover, if possible, any such tendency. Sufficient evidence of its presence may be obtained in the previous history of the candidate or in the medical examination carried out on the above lines.

Limitations of the Examination.

The examiner will also bear in mind the limitations of his examination. It is primarily and essentially a medical examination to determine physical fitness. It is not expected that the examiner will be able to pick out the future cream of airmen at this early stage, any more than at an entrance examination at the university the future leaders of the medical profession are to be recognised. The examiner passes all those who come up to his standard of physical fitness and leaves to the future training and experience the development of the individual's flying ability.

As already stated, the examiner must not be expected to decide as to which candidates have "the flying temperament" and which have not. It may be apparent at once, but, on the other hand, it is an elusive qualification and may be entirely latent until developed under actual flying experiences. Attempts to determine at the examination as to what heights the candidates should fly and what line of flying work he is best suited for are, to say the least, premature. These questions can be settled only with knowledge and precision as the result of training and experience.

The mentality of the candidate must be considered, but a low grade does not disqualify unless the examiner considers that it is so low as to amount to mental defect or deficiency. The quick, alert examiner must not mistake the slow cautious youth for an imbecile. The mental calibre, if not up to flying duties, will be sufficiently tested at the examinations which the candidate has yet to pass as a cadet before entering on actual flying, and to that test the medical examiner may safely leave the doubtful cases.

Points to be Determined.

A careful examination must be made to determine the presence of any gross or disqualifying disease. That applies in every medical examination, and the candidates must be found "fit for general service."

Over and above this the examiner has to try to determine how the important vital organs and tissues are doing their work and how they are likely to respond to conditions of stress and strain. From his examination of the human machine at rest and under ordinary conditions he has to attempt to gauge how the mechanism will work under entirely different and much more strenuous conditions. It is not a question merely as to the sounds and size of the heart, but how the whole cardio-vascular system is to stand strain and what are its reserve powers. It is not a question of percussion resonance, or breath sounds about the lungs, but how efficiently the respiratory functions will be carried out in the flying sphere. Above all, has the candidate a nervous system which is strong and stable in itself and over which he can exercise control under novel and trying experiences?

This determination of the functional powers and of the reserve powers of the vital organs is difficult, but it is the chief problem which the examiner must try to settle. He must find out wherein the candidate is weak and wherein he is strong. It is in this connexion that single and standard tests fail, because their significance as regards the candidate's functional powers has not yet been ascertained.

The examiner has to form his decision on purely medical grounds. While appreciating a candidate's keenness to become a flying officer, which may tend to cloud his memory as to some points in his medical history, the examiner must not allow such keenness to counterbalance any evidence of physical disability. While dealing courteously with any special influences from the powers that be in favour of a particular candidate, he must not allow any such influence to affect his judgment or decision. An examiner recognising his professional responsibility in deciding on the fitness of a candidate for the arduous duties of the air service should give his decision without fear and without favour.

PREVIOUS HEALTH AND ILLNESSES.

The importance of a careful investigation into the previous health and illnesses of a candidate cannot be overestimated. No examiner, however experienced, can deal sucessfully with his work if he omits this, and bases his opinion solely on tests and physical examination. It may be said that the candidate will conceal important facts in his eagerness to be passed, and many do. But with the examiner noting down his replies and cross-examining him the truth will be elicited in the majority of cases. In this inquiry also stress is to be laid on a history of special symptoms, which may be of importance in directing attention to particular organs in the physical examination which is to follow, or may be of such importance as to render the candidate unfit for flying.

The examiner, for his own guidance, might lay down some such rule as the following: Any form of constitutional or acquired disability which has rendered, or which may render, the candidate liable to attacks of loss of consciousness, lapses of memory (mind a blank), fainting, loss of vision (hemianopia, temporary amblyopia), or prostrating headache should be a definite cause of rejection.

As regards special diseases the following list comprises those about which particular inquiry should be made: Asthma, malaria, syphilis, rheumatic fever and chorea, digestive disturbances, migraine, petit mal, epilepsy, nervous debility, neurasthenia, shell shock, concussion with unconsciousness, chronic joint disease (especially of the knee), and the diseases of active foreign service. Several of these form an absolute bar to acceptance, while others must be considered from the point of view as to whether recovery has been complete or not.

The complete examination of the flying candidate requires an investigation as to his fitness from a general surgical standpoint. A special examination must also be made as to the condition of the eyes, nose, ear, and throat. The candidate's vision must be tested, and this is the only part of the examination where definite standards have to be employed. It is to be hoped that the standard of normal binocular vision will soon be established. The examination of the ear, including the labyrinth, brings up the question of vertigo and balancing. On this subject my colleague, Mr. Arthur Cheatle, has introduced various testing exercises, which are useful not only as bearing on labyrinthine efficiency but also as indications as to the nervous tone and stability generally.

The internal organs must be examined in order to exclude organic disease and to test their functional activity. We shall consider more particularly the two most important systems—namely, the cardio-vascular and the nervous.

THE CARDIO-VASCULAR SYSTEM.

Our system of examination here proceeds on somewhat different lines from those of the naval and army services. Under the term cardio-vascular system are included the heart, the arteries, the veins, and the capillaries. Two entirely separate abnormalities are recognised—namely, organic disease and cardio-vascular debility.

I.—ORGANIC DISEASE OF THE HEART AND BLOOD-VESSELS.

Cardiac Murmurs.

Organic disease of the heart is not common amongst candidates, but none the less it must be carefully examined for. The definitely disqualifying lesions, which are generally accepted in all the services, are mitral stenosis, as shown by a presystolic murmur at the apex, and aortic regurgitation, as shown by a diastolic murmur at the base Expressing this in another way, one may say that a definite murmur occurring during the period of diastole is a cause for rejection. It is not necessary to discuss why these lesions should be viewed so gravely, because medical opinion seems for once to be unanimous on the subject. As regards our own experience amongst candidates previously examined we have found a tendency to diagnose a mitral presystolic murmur when it was not there and to overlook an aortic diastolic murmur when it was present.

Apart from these two conditions, little attention is paid to murmurs, systolic in time, which are heard about the præcordia, unless they are the result of rheumatic fever or are accompanied by definite pathological changes in the heart. A healthy youth who has never had rheumatic fever and who has never had any cardiac symptoms is not to be rejected because a systolic whiff or murmur is heard about the apex or the base. In the majority of the young candidates a careful examiner will detect a systolic murmur, with its maximum intensity over the pulmonic area; this is regarded as physiological and not pathological. A basal systolic murmur due to aortic stenosis is very rare—no case has occurred in my experience—and this lesion should not be diagnosed in the absence of clear evidence of hypertrophy of the left ventricle.

If a systolic murmur is present at the apex and is regarded as due to mitral regurgitation, and if there is a history of rheumatic fever, it will probably be advisable to reject the candidate. This decision would not be based solely on the mitral lesion, but also on the tendency to recurrence of the rheumatic disease. If a systolic murmur at the apex is regarded as due to mitral regurgitation, in the absence of a history of rheumatism we base our verdict on the presence or absence of any changes in the heart as the result of the mitral lesion. If the heart is not enlarged, or hypertrophied, as regards the right or the left ventricle, and if the sounds there are clear, and if the candidate has had no symptoms of cardiac disability, he may be regarded as possessing a functionally sound heart. In other words, a mitral lesion is weighed according to the effect it has produced on the musculature of the heart and the heart's efficiency, and if no effect can be detected the cardiac lesion may be ignored.

Cardiac Irregularity.

Cardiac irregularity is not to be regarded as an indication of cardiac disease. The most of the irregularities met with amongst candidates are not associated with any form of heart disease.

The most common form is "the youthful type of irregularity," a sinus irregularity which manifests itself by a quickening of the cardiac rate during inspiration, and a slowing during expiration. Every examiner should make himself familiar with this type of irregularity, which is extremely common amongst candidates, and has in the past been a common cause of rejection for the public services. This irregularity is of no significance or importance.

The occurrence of extrasystoles or premature contractions is another not uncommon form of heart irregularity, and is usually manifested by an occasional "missed beat" discovered while one is auscultating the heart or feeling the pulse. This form of irregularity is of no importance taken by itself. If the candidate is conscious of the "missed beat" and says he can feel his heart stop and go on again, he probably has that sensitive type of nervous system which is potentially neurasthenic.

In practice no candidate is rejected for any form of sinus irregularity or because of the presence of occasional extrasystoles. The more important forms of cardiac irregularity usually associated with an abnormal rhythm of the heart, such as auricular fibrillation or auricular flutter, heart-block, &c., are very rarely met with, but are to be regarded as evidence of disqualifying heart disease. Any form of paroxysmal tachycardia is a cause for rejection.

Area of Cardiac Dullness.

If there is marked dilatation of the heart with a persistently rapid rate there is probably serious myocardial disease or infection, and the candidate should be rejected. A slight alteration in size or shape from what is usually described as "the normal heart" must not be unduly emphasised. Candidates are not to be rejected because the apex beat is on or a little outside the nipple line, or because the normal area of cardiac dullness is slightly enlarged. At the age the candidates present themselves such variations in the size of the heart are common and are not of themselves of any special importance. On the other hand, cardiac hypertrophy, usually associated with dilatation, is always pathological. If there is a definitely heaving action of the right or left ventricle, a cause for this must be looked for, and full consideration given to the underlying cause and its probable effects. Dilatation of the heart must not be confused with displacement of the heart. In many cases the apex beat may be found outside the nipple line when the candidate is standing, and drops back within that line when he lies down.

The Arteries.

Organic disease of the arteries in the form of arteriosclerosis is not often met with; it is sometimes present in the older candidates. Arterial thickening, with or without tortuosity of the vessels, is probably always the result of some form of toxæmia. If associated with renal disease or retinal changes, or cardiac changes, or definite symptoms, it is clearly a cause for rejection. If it is present without any other evidence of disease, and the candidate is physically sound, he may be accepted.

A high systolic blood pressure—namely, 130 to 150, as estimated by the sphygmometer—is often found amongst candidates, and is not of itself a cause for rejection. If the examiner considers the blood pressure too high at systole or too low during diastole, or that the "pulse pressure" is unsatisfactory he must not reject the candidate on any one of these grounds unless he finds symptoms or signs of organic disease of the heart or blood-vessels. Striking variations in the sphygmomanometric reading are met with in connexion with cardio-vascular debility and in the absence of any organic disease.

II.—CARDIO-VASCULAR DEBILITY (C.V.D.).

This is a condition which has come to occupy a position of great importance in the examination of flying candidates. As a clinical entity it may be said to have established itself owing to the war, but there is no agreement as to the underlying cause or causes of the condition. We shall therefore deal with it from a clinical point of view.

In determining the symptoms and signs and their importance we have derived evidence from two sources—namely, (1) the condition as it is met with in civil life; and (2) the condition as it is met with in the case of flying officers who have broken down with similar signs and symptoms. A study of these two conditions will help one in determining the presence of cardio-vascular debility in candidates.

Clinical Experience in Civil Life.

In civilian practice clinical experience has marked out a type of individual characterised by certain cardio-vascular phenomena, present more especially during youth, but persisting in many cases through life. There is a tendency to breathlessness, to præcordial pain, to faintness or fainting, and to a rapid and thumping action of the heart under slight provocation. The faintness is often induced by a change of posture from the horizontal to the vertical, as on rising in the morning. The subject of this condition is in a chronic state of tiredness, and slight exertion soon brings on a feeling of exhaustion. Active games or heated rooms bring giddiness, fainting, or vomiting. He will state that he suffers from "a weak circulation," that his hands and feet are usually cold, that he has chilblains in winter, and that he stands cold weather badly.

On examination we find no evidence of organic heart disease. There may be an exaggerated sinus (respiratory) irregularity, or a rapid action of the heart, or some dilatation, or systolic murmurs heard over the præcordia. The pulse is a poor one in the sense that the tension is badly sustained. There may be exaggerated pulsation in the large vessels of the neck and in the abdominal aorta. The peripheral circulation is defective, as shown by the dusky

and cold hands and lobes of the ear. There is a tendency to venous plethora, which is present also in the large abdominal veins. Functional albuminuria of the postural type—that is to say, due to a change from the recumbent to the erect position—is often present.

These are some of the chief features of cardio-vascular debility as we have recognised it in civilian life.

Cardio-vascular Debility in the Flying Man.

Let us turn now to the symptoms and signs presented by flying men who have broken down under instruction, or as the result of a minor crash, or during active service.

Amongst the common symptoms are tiredness and a sense of exhaustion easily induced by any exercise, faintness, giddiness, blurring of the vision, headache, rapid action of the heart and palpitation, præcordial pain, and breathlessness on exertion. In a large number of these cases we shall find the evidences of a defective circulation which we have described in our civilian type.

It is not necessary to assume that all these conditions are the result of a flying career, or that they denote any special aerial malign influence on a healthy individual. Rather should we infer that the new surroundings and stress had acted on an individual already possessed of cardio-vascular debility, in a more or less latent form, so as to bring out the symptoms in a striking and disqualifying way. Those who have been engaged in the study of a similar (if not identical) condition known as "soldiers' heart" (D.A.H.) have been struck by the same fact. Hume and Parkinson have found that in a large number of cases of D.A.H. symptoms of a similar kind had existed during civilian life, and had only been intensified by army service, or intercurrent illness.

Significance of the Symptom-Complex.

It may be said that we are not dealing here with any known disease. This may be admitted, but a symptom-complex such as we are dealing with has its value. If in civil life men who have this symptom-complex are found to be limited in their activities according to the degree of its manifestations we are entitled to lay some stress on it. If in the flying service many men who break down more or less easily are found to show this symptom-complex in a marked degree, we are justified in considering it of some importance. If civilian experience and that of medical invaliding boards are to be made of practical value in the flying service it is of the greatest importance to apply them at the examination of candidates. Bearing these facts in mind the examiner will seek to determine the functional power of the cardio-vascular system in a candidate. Does it show any evidence of weakness? Will it probably be strong enough to stand the causes of disturbance associated with air work, or will it probably break down under the strain?

The results of the inquiry into the candidate's previous health as to such symptoms as fainting and faintness, shortness of breath, &c., must be considered in connexion with the cardio-vascular system. The information supplied may or may not be correct, but if there has been any evidence of former cardio-vascular debility, it will usually be possible to obtain it by cross-examination. For various reasons boys who suffer from cardio-vascular debility are often sent to school with the statement that they are "delicate," or have "a weak heart," or "must not overdo games."

Examination of the Heart.

From an examination of the heart itself we learn little of its efficiency from the cardio-vascular point of view. The sounds may ring clear and true, but the cardiac action may be weak. The sounds may be blurred or reduplicated, but no evidence of a defective circulation is revealed. The apex beat may not be felt, and yet the ventricular contraction may be a powerful one. On the other hand, cardiac pulsation may strike (apparently) strongly over a considerable area of the chest wall, simply as the result of nervous excitability.

The cardiac efficiency is to be tested by its response to effort, and more especially by the degree of breathlessness induced by physical exercises. As a matter of practical experience, it may be pointed out that at the age under consideration the cardiac action is seldom inefficient, and a breakdown of myocardial contractility is not to be anticipated. The disturbances which may arise in the heart are not primarily myocardial in origin, but are most commonly nervous.

Along with other organs the muscular tissues of the heart seem to suffer secondarily under stress from a loss of tone or power, but the ordinary physical examination of the heart does not supply any definite information as to the presence or absence of this condition. While evidences of organic heart disease are absent, this type of individual shows in great variety and with great frequency systolic murmurs about the præcordia.

The Heart Rate.

A difficulty which presents itself in the case of these young candidates is that the excitement and anxiety of a medical examination leads to a rapid cardiac action. We find not uncommonly a rate of 110, 120, or 130. If this were the usual rate of the candidate's heart he would probably be rejected. As his anxiety may persist through the whole examination the increase in cardiac rate may be maintained. As very few individuals possess any control over the cardiac rate we cannot always succeed in checking the rate by calming words to the candidates.

If the increased cardiac rate is due to nervous excitement there will usually be a diminution if the candidate is placed at rest on a couch and is asked to breathe slowly and deeply. Another test employed is as follows. The candidate, lying comfortably on a couch, is asked to breathe very slowly and very deeply. The apex is then carefully auscultated for any change in rate during inspiration and expiration. If the heart rate shows a respiratory variation, more especially a definite slowing during expiration, then in all probability the excited action is not cardiac in origin, but arises from some influence outside the heart, usually nervous and temporary. The reason for this conclusion is that the slowing of the heart is vagal in origin, elicited by respiration, and such slowing does not occur in hearts quickened by myocardial disease. If, on the other hand, the cardiac rate shows no change under rest or deep respiration there is probably some permanent disturbing factor at work, such as toxæmia or latent infection. In such a case the candidate cannot be accepted and must be refused or deferred for a time.

If the heart rate is found to be moderately increased on examination, up to 100 or 110 beats per minute, and if after exercise this rate is not increased or is definitely lowered, one may conclude that the disturbance is of nervous origin and no real importance.

The quickening of the heart rate is usually of nervous origin, and as such must be taken into consideration with the other signs of nervous instability which may be found. Amongst candidates it is a very common condition, and as a medical examination has often a similar effect on seasoned warriors, too much stress must not be laid on this condition when it is nervous in origin and temporary. On the other hand, a slow pulse—namely, a rate of 60 to 70—is usually a good sign. Its presence at once excludes the numerous causes of disturbance or disease leading to a rapid cardiac action. It is also helpful in enabling one to judge more accurately as to the state of the circulation generally than when an excited and rapid heart action is present.

The Pulse.

Passing from the heart to the larger blood-vessels, we find valuable information supplied by the pulse. In a good type of candidate the pulse at the wrist is of good volume, of well-sustained tension between the beats, and does not show any sudden rise or fall during the beats. Elevation of the hand while the pulse is being felt may show a brief falling off in strength, but this soon passes off and the pulse quickly steadies itself whatever position the candidate assumes and whether the hand is lowered or raised.

In another type of candidate (C.V.D.) we find a pulse of a different kind. The volume may be good but the tension is badly sustained. The beat may be strong, may appear stronger than usual, but it is quick and snappy, and the tension falls abruptly. We seem to have a sudden filling and a sudden emptying of the vessel, which in well-marked cases is strongly suggestive of the collapsing pulse of Graves's disease or aortic regurgitation.

Suppose this condition is present when the candidate is lying on a couch with the arm at his side. If the arm is raised vertically so that the radial artery at the wrist is some 2 feet above the shoulder we find the above conditions are

intensified to a marked extent. If the tension of the pulse (horizontal) seemed rather poorly sustained there is no doubt about it when the arm is raised, and, further, there is no recovery of tension while the arm is raised. It is found useful to make this test by feeling both pulses (radial) at the same time, the candidate's one arm being raised and the other horizontal or pendant. One can then feel clearly the differences in the two pulses which has just been described.

In extreme cases of C.V.D. we often find that the pulse falls away so markedly with the arm elevated as to become almost imperceptible. The beat itself is so weak and feeble that one cannot make out a diminution in tension between the beats. Whatever the cardiac driving power may be, its force seems to have been largely dissipated before it reaches the wrist. The healthy type of candidate seems to have circulatory organs always "on duty," as it were, ready to respond to any change in the circulatory conditions, and able to maintain a steady circulation under altered conditions. The C.V.D. type, on the other hand, seems to have a circulation always "off duty," as it were, never ready to respond to a sudden change in the circulatory conditions, and unable to main a steady circulation under altered conditions.

Readings taken by the sphygmomanometer in a number of C.V.D. cases vary much, but they seem to show that the systolic pressure is normal or raised while the diastolic pressure is normal or lowered. In other words, the "pulse pressure" is usually above 50, and may be considerably increased.

The Peripheral Circulation.

As regards the peripheral circulation, we expect a good type of candidate to present signs of a healthy circulation in the hands and lobes of the ear. The colour should be light red or ruddy, and after pressure the superficial circulation should quickly restore the normal colour, while the extremities should be warm under the ordinary conditions of examination.

In a C.V.D. subject we find that the hands are dusky and cold, and that on pressure the pale patch fades away very slowly to be replaced by the same blue colour. When the limb is elevated above the head the force of gravity slowly removes the cyanotic hue from the extremity, which may become quite pale in colour. One is not surprised to find that chilblains are common in these subjects or that they suffer much from cold hands and feet.

A few candidates have shown or given a history of white and cold hands instead of blue. This points to a condition of vaso-motor spasm in the arterioles rather than relaxation. It is a more crippling condition as regards the use of the hands, and a history of "white fingers" or evidences of the condition should disqualify, as it would probably be intensified under flying conditions. We have met with some flying officers permanently disabled for air work by this condition.

Venous Plethora.

A tendency to venous plethora undoubtedly exists in these C.V.D. subjects, but is difficult to determine by physical signs at an examination. It is probable that the symptoms in these cases are elicited under exertion or excitement by overfilling of the abdominal veins, the so-called "splanchnic flooding" and fainting. The venous plethora in the abdomen is probably associated with the lack of tone in the abdominal muscles, to which reference will be made later. It may be shown in some cases, if the examiner presses both hands on the abdomen, by a swelling up and pulsation in the veins of the neck.

Conclusions Reached from the Physical Signs.

The above may be termed the physical signs by which we seek to determine the presence or absence of C.V.D. In themselves they do not indicate inability to perform the physical duties of ordinary life, nor do they imply ill health, although they may follow an illness. But the examiner's task is in a sense a prophetic one, and the question to be decided is as to whether a candidate showing the above condition of the heart and blood-vessels has a strong and stable cardio-vascular system, fitted for the duties of a flying officer. To this the answer is that he has not, so far as we can judge from civilian practice, from army experience, and from experience of flying officers who have broken down.

Practical Tests.

It must be admitted that practical tests as regards the efficiency of the cardio-vascular system leave much to be desired. A candidate labouring under the excitement of a medical examination is not in a condition to show his best or his usual form at testing exercises. Before he has been asked to do anything we may notice the quickened pulse-rate and the quickened breathing, of nervous origin. The tests which we should like to apply are not available in the limited accommodation of the examination room. The tests we do employ tend to be of an artificial character, and such as the candidate has not been accustomed to do, and such as he would often do after a little practice. Hence the late comers in the day may have had time to practise successfully the tests which the early comers have described to them!

One tests the effect on the heart rate and respiration of a definite amount of physical exertion such as that of swinging the raised arms down to the toes four times, or rising from the floor on one foot on to a chair and back again four times. The pulse-rate and respiration-rate are then counted, and the time taken until these rates return to normal (or to the candidate's rate at rest) is noted. A quick return to normal, say under 30 seconds, is regarded as a healthy sign, while a delay of over two minutes is suggestive of C.V.D. Perhaps more valuable than the heart rate is the quickened and even laboured breathing which follows this moderate exercise in many cases of C.V.D.

A greater amount of physical exertion may be employed by making the candidate march quickly up and down the room, or up and down a stair, and noting the effect on the pulse and respiration. No absolute standards can be given, but the examiner notes whether the result appears to be normal or excessive.

Another test employed has been that of breath-holding. The candidate, when seated, is directed to expire as deeply as possible, to inspire fully, and then to hold his breath as long as possible while the nose is clipped or closed with the fingers. A minimum of 45 seconds has been suggested as the pass standard. There is a scientific preciseness as well as plausibility about this test which has rendered it popular with some examiners. A failure to attain to the pass standard has been ascribed to an inability to obtain sufficient oxygen owing to a low "vital capacity," or to hypersensitivity, or to diminished oxygen pressure, or to the fact that the candidate uses up his available oxygen more rapidly than a normal man. There is evidently room for more scientific inquiry to determine what the test really does imply and mean, and its value as a test for aviation purposes. A high standard in breath-holding would seem to be more called for in sub-aqueous than in aerial pursuits.

A Difficulty in Exercise Tests.

One great difficulty in establishing any satisfactory exercise tests for the efficiency of the cardio-vascular system lies in this—that other systems are necessarily brought into action. If the exercise test is unsatisfactory the question arises as to how far the result was due to the cardio-vascular system and how far to some other system.

For instance, if after a brisk walk the candidate's pulse-rate remains unduly high, and his breathing is unduly laboured, we shall have to distinguish between the effects of exercise on (1) the cardio-vascular system, (2) the respiratory muscles, (3) the muscles involved in locomotion, (4) the pulmonary organs, and (5) the nervous controlling and coördinating centres. We have not been testing the cardio-vascular system alone, but have also of necessity brought in those other complicating factors.

When we come to discuss the method of summing up the results of the candidate's examination we shall find that this difficulty is often solved by the fact that, as a rule, evidences (symptoms and physical signs) of C.V.D. do not stand alone, but are accompanied by signs of debility in other tissues and organs. A very common cause of rejection is a combination of cardio-vascular and nervous debility.

THE NERVOUS SYSTEM.

Gross organic disease of the brain or spinal cord is not often met with amongst candidates. An old lesion like infantile paralysis, which may render a man unfit for general service, is no bar to flying work, provided that the functional efficiency of the affected limb or limbs meets the requirements of the flying service.

Disturbances of nervous function, either masked, as in the form of petit mal or asthma, or open in the form of over-excitability or instability, are very common amongst candidates. Any pre-existing nervous weakness is apt to be intensified by the conditions of a flying officer's life. The youth who stammered as a boy, but has been free from the habit for some years, resumes it when he has been in the flying service for a time. The youth who never stammered before, but whose father had a stammer, develops the condition under the stress of flying work. The subject of a previous nervous breakdown at school will probably have another similar attack after a slight crash. In this part of the examination the history of any previous nervous disability, personal or familial, plays an important part.

Points Considered in Examination of the Nervous System.

As the nervous system is exposed to considerable strain in the flying service, we wish to have some tests to determine the *nervous tone* and *staying power*. The task, however, is not easy owing to the absence of any recognised standards. We have to recognise amongst the candidates a great variety of temperaments. We meet with the level-headed and calm, the keen and excitable, the somewhat dull and irresponsive, the youthful Hercules with sluggish mentality, and the absolutely stolid type. Each and all of these types may do good flying service in different departments of the work. Some of the excitable may become notable flying men; some of the phlegmatic may carry out routine duties for months without achieving anything brilliant, or, on the other hand, may become exceedingly good pilots.

The point to which we have directed attention in the selection is not whether a man is nervous and excitable, or dull and phlegmatic, but what *control* can he exercise. Before making a speech a public speaker may be intensely nervous, but, when he begins, calm and clear owing to the control which he has learned to maintain over himself. So in the case of nervous and excitable young men, the question is as to how much control they already possess, or are capable of developing, in view of the strain that lies ahead. It is impossible to pass a complete and final judgment on this question at one medical examination. Those who have been accepted and passed should also be carefully observed as to the above points at the flying schools by the C.O.'s and instructors, who see them at work under the actual conditions of service.

Another point which seems to have been brought out by experience is this, that the nervous type of individual, the man without much self-control, is apt to crack up readily under the stress of the minor accidents of training—e.g., a bad landing or a slight crash. There may be no physical injury, but the nervous control, such as it was, seems to be quickly and irretrievably lost. It is clear that a very large number of flying officers who have broken down never possessed a nervous system of even ordinary stability.

One must allow for the effects of excitement on the nervous system under a medical examination. This can usually be estimated at its proper value by putting the candidate at his ease. It may be considerably increased if the candidate has been kept waiting for some hours, or has been travelling all night, or is convalescing from acute illness. These points must be inquired into and taken into consideration.

Signs of Nervous Instability.

The condition of the deep reflexes is tested. As a rule they are fairly active in healthy candidates. An over-excitability and exaggeration of the knee-jerks and elbow-jerks has come to be regarded as an indication of nervous debility. When a brisk muscular response follows on tapping anywhere in the extremities there is positive evidence of an over-excitable nervous system. We do not find that these conditions stand alone, but that the candidate shows other signs of nervous instability. We have also found them present in flying men who have broken down in the service from nervous causes.

A persistent dilatation of the pupils with an excitable manner is regarded as suspicious of undue nervous excitability.

General tremulousness is not to be reckoned as a good sign, although it may be present merely as the result of excitement at the medical examination. A candidate is asked to hold out his hands and to close his eyes. The presence of tremor in the fingers and eyelids is looked for, and if this is constant and pronounced it is regarded as indicative of nervous instability.

Considerable emphasis is laid on the results of the balancing test, because healthy young men have no difficulty in balancing themselves steadily first on one foot and then on the other with the eyes closed and the hands at the sides. Many break down hopelessly from the start, and seem quite unable to maintain any stability on one foot. A man of this type will show other signs of nervous or neuro-muscular instability sufficient to cause his rejection. The pass standard requires that a candidate should be able to stand quietly and steadily on one foot for 15 seconds.

A candidate who sleeps soundly is usually healthy. On the other hand, a man who sleeps badly and who wakes unrefreshed and tired will usually have associated (as cause or effect) a weakened nervous system.

SUMMING-UP AND ASSESSING.

A certain number of candidates are eliminated because of some definite medical or surgical disease, or of their previous medical history, or of other clearly disqualifying condition.

Another group fall out, not from actual disease, but because the physique or cardio-vascular system or nervous system is so much below par as to show clearly that failure in the flying service would certainly follow.

Borderland Cases.

These two classes do not, as a rule, present much difficulty, but there is a third group of what may be termed borderland cases, in which the assessing of the candidate's fitness is no easy task. There may be no reasonable objection to his undertaking ground duties, but what we have to do is to form an estimate as to his stability or staying power for air work. Is the candidate suited for the special work during the training period and for the stress and strain of active service which will follow? As already stated, we are unwilling to base our decision on rigid single tests, first because it is easy to overestimate their importance, and, secondly, because we have not sufficient knowledge as to what they portend. The path of prognostic medicine is strewn with their discarded and dishonoured remains. In these borderland cases we lay most stress on the summing-up of the conditions found in connexion with the physique, the cardio-vascular system, and the nervous system.

The result of experience has been to show that if one of these systems is weak as a whole, functionally considered, there are several or many evidences to be found on testing. For example, if we find a weak flabby pulse we shall also usually find other evidences that a steady, strong, and effective circulation is not being maintained. If we find that a candidate is very unsteady and tremulous, we shall probably obtain other evidences of an unstable and imperfectly controlled nervous system. Further, as a matter of experience we find that when there are signs of cardio-vascular debility in a candidate the examination also reveals signs of nervous debility, and *vice versa*. It would appear that the two systems are often functionally weak in the same individual, so that in weighing the evidence we have to combine the results of the examination. A candidate may have certain signs of nervous weakness, not sufficiently pronounced to lead to his rejection, but when signs of a defective circulation are also present the combined weaknesses are sufficient to condemn him.

Not infrequently when the general physique of the cases which appear to be unsuitable from some systemic weakness is considered we shall find that it is definitely below the high standards and often distinctly poor.

Some Exceptions: Deferring Decision.

While the above experiences are common there are, naturally, exceptions met with. The candidate may have some weak points as regards the cardio-vascular system but be quite satisfactory as regards physique and nervous stability. He may be apparently weak in some points as to nervous control, but he may show a most satisfactory physique and cardio-vascular system. In such cases we should regard the weak points as being counterbalanced and compensated for by the strong ones, so far as the assessing is concerned.

"Be to his faults a little blind and to his virtues ever kind."

It is to be recognised that at the age we are dealing with the full development of the candidate has often not yet been

reached, and that while functional development in some parts of the body may be complete, it may be incomplete in others. It is also to be recognised that the effects of recent illness, of night travelling, or of the excitement of a medical examination, may cause temporary and local effects which must not be too much emphasised. For these reasons we do not reject candidates because of some evidences of defective functional powers, provided that they are counterbalanced by the presence of healthy functions generally, or can be explained by some temporary disturbance.

In some cases a final decision has to be deferred. A candidate suffering from active illness (for example, tonsillitis), or from recent acute illness, is not at his best, and if there is any doubt as to his suitability a final decision should be deferred until a further examination after his recovery. The case of the undeveloped boy presents some difficulty. He may be all right as far as he goes—but he has not gone far enough. It would be courting disaster to put him to work and strain for which he is not yet physically fitted. The examiner should state definitely about such a candidate that he is too undeveloped for flying work, and defer a final decision for 6 or 12 months. This period ought to be spent in physical training.

In the course of examination certain remedial defects or diseases may be discovered in otherwise eligible candidates which render them unsuited for air duties. In such cases the necessary treatment is to be ordered and the final decision deferred until a later examination, when the result of treatment can be estimated.

Suitability of Candidates for Various Kinds of Work.

It is not advisable to ear-mark the candidates who pass the medical examination for the special line of flying work they are fitted for. In the past we have made a distinction between those who were passed as pilots and those who were passed as observers. The latter were not quite up to the standard of the former, medically considered, and it was held that in the air the pilot had the more responsible post as, in addition to the control of his plane, his own life and that of the observer depended on his skill and judgment and self-control. On the other hand, if the observer broke down in the air the results would not probably be very serious. With the great intensification of aerial fighting that has taken place, and with the great nervous strain now imposed on both pilot and observer I am inclined to think that only first-class men should be passed as observers. Their individual responsibility may not be so great as in the case of pilots, but their duties call for physical and mental fitness of the highest order.

As regards the question of nervous strain there is no doubt that an observer, flying with a pilot he does not know or in whom he has lost confidence, may be much more strained, in a passive way, than the pilot whose mind is occupied with the immediate duties of flying his machine. He is so strained, in fact, in many cases that he is anxious to qualify as a pilot himself, in order to get relief at duties which he believes to be less onerous. Experience has confirmed this view, and many observers by becoming pilots—often very good ones—have probably been saved from a nervous breakdown. For these reasons, at the medical examination we are disposed to establish the same pass standard for pilots and for observers.

There are many types of work and many types of machine in the air force, but at the examination stage it is necessary to pass only first-class men. After qualifying they will be classified according to the type of work they show special aptitude for, and for which their physical powers and skill are best suited. Some will remain as home instructors, others will go in for scouting machines, bombing machines, low-flying machines, high-flying machines, &c. So far as their aptitudes, medically considered, are concerned, we think that there should not be an attempt at the examination to define them, or to impose any limitations as to the height at which a candidate should fly, or to specify the exact nature of his future work—e.g., artillery pilot, ferry pilot, &c. These matters can only be satisfactorily settled after the pilot has finished his regular course of training, when the commanding officer, the instructor, and the medical officer will have evidence before them of what actual experience has shown regarding each individual pilot. The examiner will do well to refrain from attempting to guess on limited knowledge what this actual experience will be.

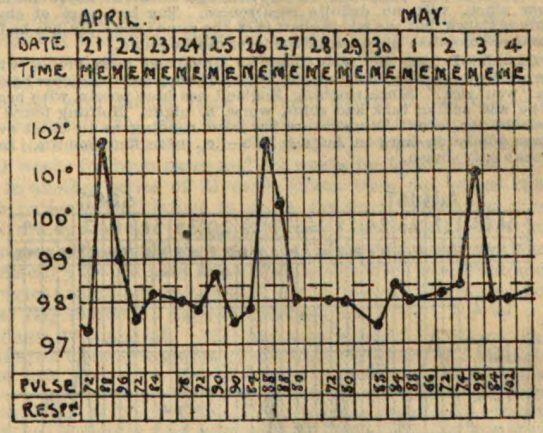
TRENCH FEVER CACHEXIA.

BY R. D. RUDOLF, C.B.E., M.D. EDIN., F.R.C.P. LOND.,
COLONEL, C.A.M.C.; CONSULTING PHYSICIAN, CANADIAN FORCES IN ENGLAND.

Trench fever has now become a "recognised disease" in the Army, and an enormous wastage of man power has been due to it.

Types of Trench Fever.

Major J. W. McNee, who early in the war did such good work on the condition, originally described two types of the disease—(1) the short type, and (2) the long one. The short type was characterised by a continued fever which lasted some eight days, then came down by crisis and was usually followed by a single short relapse, and then the disease was over. The long type, on the other hand, commenced with a short spell of fever, lasting perhaps four days, but this was followed some five to ten days later by a relapse of one or two days' duration, and such relapses usually recurred a number of times, and might do so for weeks or even months. Major McNee showed by inoculation experiments that these types were due to the same infection, in that volunteers inoculated with the blood of one type might sicken with either form of the fever. He stated that the long type of trench fever averaged four to six weeks, during which recurrences occurred at intervals, but he also said that "oscillation of temperature, with returns of pains and headache, may recur for weeks and (rarely) months." We now know this to be very true, as in hospitals in England we often come across such cases. Case 1 (Private M.) (see Chart 1) is an example of such, but they may recur for much longer than three months.



1

The Army Commission upon Trench Fever described three forms of the fever[1]: (*a*) Relapsing class, (*b*) single short bout and no relapse, (*c*) prolonged initial fever. Class (*a*) had two subclasses: (1) Regularly relapsing with normal intervals, and (2) irregular relapsing, in which the intervals between relapses are not so definite, or if the intervals are definite the temperature remains above normal. They state that the "irregular fever may last for several weeks," and one chart given in their report shows it still present on the sixtieth day, after which the patient was evacuated to England.

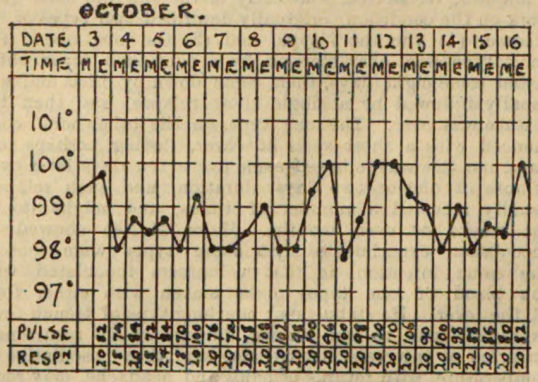
The American Red Cross Commission on Trench Fever, in their recent report, say that cases may last for 60 days or more, and the Hampstead Trench Fever Commission found the blood infective as late as the seventy-ninth day.

Cachectic Cases.

In one's work in the Canadian hospitals in England it is a very common thing to come across men who are debilitated and anæmic and suffer from pains, chiefly in the shins. If the temperature of these men be taken it is often found (although not in every case) to be running a little too high. If one looks at a *normal* temperature chart endways the

[1] Brit. Med. Jour., Jan. 19th, 1918, p. 91.

tracing tends to run below the 98·4° line; in other words, the normal temperature—so-called—is usually below the so-called normal temperature line marked on the charts. If, now, the temperature chart of a case such as we are describing be looked at in the same way, the average temperature will be seen to be set a degree or two higher than the normal, with occasional rises to 100° or perhaps 101°. A glance at the medical history sheets of these men will usually show that they were invalided from France as cases of P.U.O. or as trench fever, it may have been months or even over a year before.

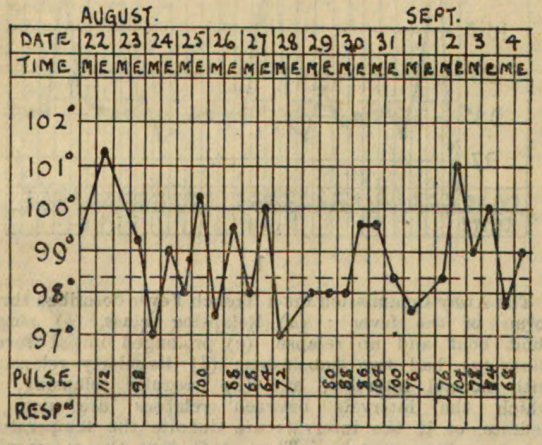


2

Cases 2, 3, 4, 5, and 6 are examples of this chronic fever, and they could be duplicated indefinitely:—

CASE 2.—Private S. (See Chart 2.) Took ill on July 28th, and was invalided as trench fever. Since then felt poorly, with aching shins. Temperature has remained on the average about 2° above normal ever since, with no definite recurrences. The last part of chart only is shown, but the whole chart is of the same type. He has had it for three months; no cause for the fever can be found.

CASE 3.—Private H. (See Chart 3.) Invalided from France with trench fever on May 23rd and had been suffering for some days before he "went sick." Since reaching England has been poorly, with headache and aching back and shins, worse at night. Nothing found to account for fever. Temperature has been running as in chart ever since admission here on August 10th—i.e., over four months. Last week's only shown.



3

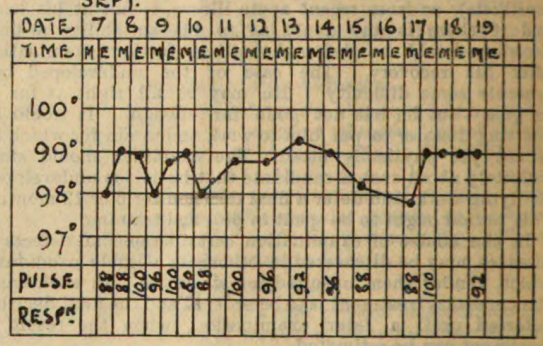
CASE 4.—Private M. (See Chart 4.) Invalided from France on April 19th last with trench fever; had been ill some time before. Ever since has been in same hospital and temperature running above normal at some time in the day, as shown in piece of chart reproduced. Still feeling poorly and has aching shins. Nothing found to account for condition.

CASE 5.—Private G. (See Chart 5.) Was invalided from France as trench fever, Oct. 17th, 1917, and had been ill for three weeks before that. Has been feeling out of sorts ever since, with sore shins that get easier on exercise. His medical history sheet shows that at various hospitals he had slight fever. Was treated for the fever in February and March with "606" (Wassermann was negative), but without benefit. Now, Sept. 30th, at a Canadian hospital, and chart of temperature for last week shows slight irregular fever. Nothing found to account for it. Thus he has been ill for at least a year, and is no better now than when he was invalided in October, 1917.

CASE 6.—Private E. Complains of pains in legs and small of back. Duration one year. History: Two weeks ill in France and invalided 29-10-17 as "trench fever." *Epsom*: Medical history sheet says 30-1-18. "On admission pain in legs below knee. No swelling. Urine negative. Remedial gymnastics; some improvement. Fit for discharge." No. 11, *C.G.H., Moore Barracks Hospital*: 27-6-18—15-7-18. M.H.S. "Headache, pains in body and shins. Temperature elevated. Recovery. Transferred to Cooden Hospital. Urine negative." Now has Major Carmalt Jones's areas of hyperæsthesia. Temperature, August 13th to Sept. 11th, was 97-99·2°.

Diagnosis.

In instances of slight rise of temperature, like those here shown, tuberculosis is naturally suspected, but in the great majority of the cases that I have carefully investigated in this respect there has been nothing to confirm the suspicion.

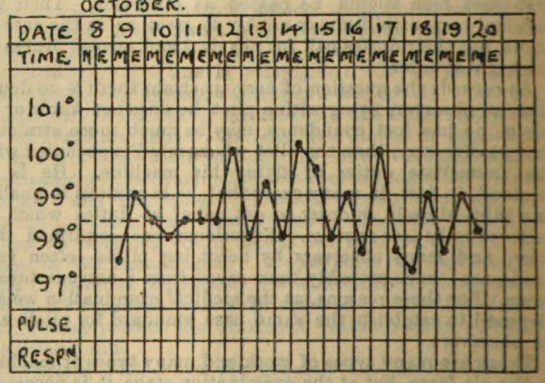


4

During some two years spent in base hospitals in France early in the war I saw many cases in which we were puzzled to account for just such slight chronic fevers, and, looking back on them now, it seems to me that they were examples of this trench fever cachexia, as one might well term it.

I mentioned above that the rise in temperature is not present in every case, because it is a common thing to see a man with the same appearance and same aching shins as the others who have no fever. Such cases may correspond to the afebrile type of malarial cachexia.

As regards the other symptoms of this chronic condition, one finds commonly that the spleen is enlarged, so that it is just palpable, and it is abnormally hard. I have observed no skin eruption. Blood examinations have shown nothing



5

except a slight anæmia and occasionally a slightly raised leucocyte count. There is usually a relative rise in the lymphocytes, but according to D. L. Tate and J. W. McLeod, *M.C.*,[2] such a relative rise in lymphocytes is the rule in healthy soldiers.

I was much interested in a paper by Major D. W. Carmalt Jones[3] in which he shows that skin hyperæsthesia of a peculiar distribution is frequently present in trench fever, and as far as a few observations of my own (made since reading this paper) go this is so in most of these chronic cases. Thus, Private E., Case 6, showed hyperæsthesia exactly as described by Major Jones. These areas correspond to the eighth cervical, first and eighth dorsal, and all the

[2] THE LANCET, April 27th, 1918, p. 603.
[3] THE LANCET, Oct. 5th, 1918, p. 443.

lumbar segments of the cord. Major Jones states that this distribution of hyperæsthesia is found in malaria and trench fever, and in no other disease. If these findings are confirmed it may be of great help in the diagnosis of these chronic subjects of trench fever, who are apt sometimes to be considered as "lead swingers" or, at least, exaggerators, when they are really suffering from a definite and disabling condition.

The question of how long this chronic trench fever may last cannot yet be settled. The longest duration that I have yet noticed is a little over one year, but it is probable that it may go on for much longer than this. Patients are usually not very ill—only in low general health, with various pains—and so they are soon transferred to a convalescent camp, or put in low categories, where their slight fever is apt to be overlooked. Since I have asked at our convalescent hospitals that such cases have their temperatures taken regularly I have found a number who would otherwise probably have been missed. The resemblance of this condition to malarial cachexia is, in many ways, so great that I venture to suggest the name—trench fever cachexia—for it.

A NOTE ON THE VALUE OF GERMINATED BEANS IN THE TREATMENT OF SCURVY,

AND SOME POINTS IN PROPHYLAXIS.

BY H. W. WILTSHIRE, *D.S.O.*, M.D. CAMB., F.R.C.P. LOND.,

PHYSICIAN, KING'S COLLEGE HOSPITAL; TEMPORARY MAJOR, R.A.M.C., NO. — GENERAL HOSPITAL.

I.—*The Value of Germinated Beans in Treatment.*

IN describing the distribution among foodstuffs of the vitamines needed for the prevention of beri-beri and scurvy Dr. Harriette Chick and Miss E. Margaret Hume[1] have demonstrated by animal experiments that germinated pulses are richly endowed with antiscorbutic vitamine, and they make the following practical suggestion: "To prevent scurvy, if a supply of fresh fruit or vegetables is not procurable, germinated pulses should be added to the diet."

Many Serbian soldiers were treated for scurvy in this hospital in 1917, and when the disease became prevalent again this year an attempt was made to test the value of these germinated pulses in treatment. Unfortunately, no suitable seeds were forthcoming for some time. All the lentils supplied were decorticated and so would not germinate, peas could not be obtained, and beans, though expected daily, took over a month to arrive. In the meantime over three-quarters of the clinical material, including all the best cases, had been admitted and treated by other means. After beans were at last received comparatively few and slight cases became available for the test, but the results obtained were so good that they are worth recording.

Haricot beans were prepared according to the directions given in an appendix to the article quoted above. They were first soaked in clean water for 24 hours and then placed in tin trays for 48 hours to germinate. Old ration biscuit tins, cut in half longitudinally and freely perforated with holes, were found serviceable for this purpose; they were easy to make, clean, and handle, and each half held 7 pounds of beans—a day's dose for 28 patients. Since germination takes about 48 hours at a temperature of 60° F., it can easily be carried out in this country in May, when the mean temperature is 67°. The whole process is very simple, the only essentials being that the seeds must be kept moist, but not shut off from free circulation of air. After germination ten minutes boiling was ample to fit the beans for eating.

In addition to general use for many patients, two wards, each containing 27 beds, were specially devoted to the purpose of comparing the therapeutic values of these germinated beans and fresh lemon juice. Scurvy cases were admitted to these two wards alternately without selection. In one ward each patient was given 4 oz. of fresh lemon juice daily, the juice being expressed in the ward, sweetened slightly, and given as a measured dose by the sister. In the other ward each patient received a portion of germinated beans which had weighed 4 oz. in the dry state, half being taken at dinner and half at tea. In respect of other forms of treatment, such as tonics and local treatment to the mouth, no difference was made between the two wards.

A certain amount of prejudice against the beans had to be contended with. Though perfectly good to eat, it cannot be said that they always looked appetising, and some with a dark husk had a disagreeable sour taste. These disadvantages might have been masked by mixing the beans in a general stew, but it was thought better to serve them apart in order to ensure some accuracy of dosage and that the cooking should be limited to the shortest possible time. Apparently, however, the greatest difficulty was based on the fact that these beans are regarded as pig food by some Serbs, and this necessitated frequent explanation of their functions through an interpreter.

Since the cases were mild and presented but slight changes, it was not easy to make comparisons. In no case did fresh scorbutic signs appear after treatment was started, and in many local lesions were limited to the gums and the hair follicles. The degree of general cachexia present was not a safe criterion of the severity of the disease, because in many instances it was partly due to chronic malaria. Hair follicle changes are not a good guide to progress, since they always take many weeks to return to normal, however quickly the active tendency may be abolished. Alteration in the condition of the gums seemed to be the best index, although allowance had to be made for the presence of dental caries and previous pyorrhœa alveolaris.

In the special wards 30 patients were treated throughout with lemon juice, and 27 with beans. Contrasting them as regards severity of disease at the commencement of treatment, those treated with beans were, on the whole, slightly worse. The difference would be too small to mention, save that it justifies the definite statement that the bean cases were certainly as severe as the lemon cases. Comparing the results of treatment, there is a small but definite difference in favour of those treated with beans, 70·4 per cent. being cured within four weeks, as against 53·4 per cent. of those treated with lemon juice. These figures favour the bean cases unduly, the real difference being better expressed by the time taken for the gums to return to normal, which was 3·1 weeks for bean cases and 3·4 weeks for lemon cases.

In another series of 21 cases beans were not given until the patients had failed to make satisfactory progress after an average of four weeks' treatment in hospital by other means. These, although they had shown themselves rather refractory to ordinary treatment, all showed acceleration of progress when put on the beans, and in some the difference was very marked. For example:—

CASE 17.—Age 51. No previous scurvy. Patient had suffered from symptoms of scurvy, sore gums and pains in the legs, for three weeks before admission to hospital at X——. He was transferred to this hospital after 25 days' treatment at X——. On admission his gums still showed marked swelling and tendency to bleed, but there was no dental sepsis to delay healing. The hair follicles on the front of the legs and thighs showed a few fresh petechial hæmorrhages. There were no big muscle or joint hæmorrhages. General anæmia was marked. After 26 days' further treatment with 4 oz. of lemon juice daily, local treatment to the gums by hydrogen peroxide and tincture of iodine, and administration of an iron and arsenic tonic, so little improvement was seen that the treatment was changed by the simple substitution of the lemon juice by 4 oz. of germinated beans. In five days definite improvement was apparent, in 13 days the gums were noted as practically normal and in 20 days as quite normal.

These clinical results, then, confirm the experimental results of Dr. Chick and Miss Hume, and permit the definite conclusion that dry beans develop, upon germination, an amount of antiscorbutic vitamine at least equal to, if not greater than, that contained in fresh lemon juice.

II.—*Deductions from Consideration of the Rations upon which our Patients became Scorbutic.*

(*a*) *Meat.*—Of 132 cases of scurvy whose previous diet was investigated last year all had received a ration of frozen fresh meat practically every day; and of 175 investigated this year very few had received it less than three times a week. Fresh raw meat is known to contain a small amount of antiscorbutic vitamine. To what extent freezing and subsequent cooking are respectively responsible for the destruction of this vitamine remains uncertain, but it is obvious that between them they render meat practically useless as

[1] Harriette Chick and E. Margaret Hume: The Distribution Among Foodstuffs (especially those Suitable for the Rationing of Armies) of the Substances Required for the Prevention of (*a*) Beri-beri, and (*b*) Scurvy, Journal of the R.A.M.C., xxix., No. 2, August, 1917, p. 121.

an antiscorbutic. In the case of tinned meat the vitamine seems to be completely destroyed by the temperature needed in the process of tinning, so that for practical purposes the meat-supply of troops in the field must be regarded as totally devoid of antiscorbutic properties.

(*b*) *Lime juice.*—In the past lime juice had a well-deserved reputation as an antiscorbutic. The vast majority of the patients admitted to this hospital had never received a single dose. Three, however, were exceptions, having developed scurvy after taking a small quantity every day for a month. These become significant in conjunction with the fact that Dr. Chick and Miss Hume found by experiment that modern preserved lime juice has but feeble antiscorbutic power, and suggest that it would be unwise to place too much reliance upon modern supplies for prophylaxis. Probably, as suggested by Dr. Chick and Miss Hume, the lime vitamines are destroyed by modern methods of manufacture.[2]

(*c*) *Fresh fruit.*—According to their own statements, not one of the patients seen this year or last year had received any fresh fruit previous to admission to hospital. Oranges and lemons become available in the early spring, but even when a sufficient quantity can be obtained they are difficult to store and transport, owing to their bulk and perishable nature. This difficulty seems to have prevented them from reaching the troops at the front last year, and would operate in the same way in future. Further, these fruits cannot be obtained in sufficient quantity in the early months of the winter, the time when they are most needed to combat the early stages of vitamine deficiency.

(*d*) *Vegetables.*—In the last two winters the vitamines received by scurvy patients before admission to hospital had been limited to those contained in potatoes and onions, with the addition, late in the season, of spinach. The potatoes, when issued, were always greatly diluted with rice, so that the amount received by each man was very small. This year out of 175 patients 101 stated that their weekly allowance of vegetables had been one, or at most two, issues of potatoes with rice, and one issue of onions. Most of these were admitted early in the season. Fifty-eight men, most of whom were admitted rather later, had fared better, receiving potatoes with rice twice a week, onions once or twice a week, and spinach once or twice a week. This should be a fairly generous supply of vitamine, and is unlikely to be exceeded next winter, but the fact remains that these men became scorbutic.

Sixteen patients were of special interest, because their diet for a month before admission should have contained sufficient vitamine not merely to prevent scurvy but actually to cure it. Eleven of these had received "plenty" of onions daily, most of them having also had potatoes with rice twice a week and spinach twice a week. Two, in addition to the above, had also received a small dose of lime juice every day, and the remaining three had received spinach every day. Now, onions, potatoes, and presumably spinach are very rich in antiscorbutic vitamine in the raw state. Granted that these men may have reached a serious stage of vitamine deficiency before their diet became so generous, the fact that they did develop scurvy on the above diets is difficult to explain except on the assumption that nearly all the antiscorbutic vitamine of the vegetables must have been destroyed in the process of cooking. This point is referred to later.

III.—*Conclusions Regarding Preventive Measures for the Coming Winter.*

(*a*) *Preventive measures should be commenced not later than the end of November and should be continued through the whole winter.*—It is essential to remember that the occurrence of the first case of scurvy in an army does not mark the beginning of vitamine deficiency. There is a prescorbutic stage, comparable to the incubation period of infective disease, during which, although the troops may appear to be in excellent health, they are in reality far from physically fit. In the case of troops rationed as the Serbian front line regiments were during the last two winters the duration of this stage probably varies between two and four months. Apart from the possible occurrence of clinical scurvy later on, so long as an army is in this prescorbutic stage of vitamine deficiency it is in danger of breaking down from various causes, such as extra physical stress, exposure to severe weather, or the presence of epidemic infections. In other words, an army deficient in vitamine is an army of deficient vitality, although until recognisable scurvy actually breaks out there is nothing to demonstrate the fact and serve as a warning.

During the last two spring seasons scurvy was sufficiently prevalent amongst Serbian troops to show that the Serbian Army, as a whole, was suffering from this vitamine deficiency to a serious extent. Clinical scurvy appeared in November, and continued until May. Vitamine deficiency must have commenced in November and continued until May, so that in any army placed under similar conditions in the future preventive measures should begin not later than the end of November, and be continued throughout the winter.

(*b*) *The destruction of antiscorbutic vitamine which takes place in cooking must be avoided as far as possible.*—The exact mechanism of this destruction is not known, but it is generally allowed that vegetables lose antiscorbutic power when cooked, and some of our patients mentioned above afford clinical proof of the fact. Simple heat and altered chemical reaction are both under suspicion as the destructive agents. Dr. Chick and Miss Hume quote an experiment which shows that cabbage leaves lose half their antiscorbutic power when boiled for half an hour, but more experimental data dealing with this point are needed.

Recently Harden and Zilva[3] have shown that the antiscorbutic principle of orange juice is rapidly and permanently destroyed when the juice is made N/20, or N/50, alkaline with caustic soda, and they suggest that any cooking entailing alkalinity will injure the antiscorbutic potency of the substance cooked. Army cooking of vegetables does not entail alkalinity. Some salt is always added to the water in which vegetables are boiled, and this may be either "issue" salt or salt in which bacon has been packed. In distilled water both of these give a solution which is neutral to litmus and is certainly not alkaline to phenolphthalein. A raw potato is acid to litmus and it remains acid when fully cooked. The water in which potatoes have been cooked remains neutral. Onions are acid when raw, and not only remain acid when fully cooked, but impart a definitely acid reaction to the water in which they have been boiled. The same is true of germinated beans. These also not only remain acid when cooked, but impart some acidity to the water in which they have been boiled. In consequence, the question of alkalinity produced by cooking does not exist as far as Army methods are concerned, and in the present state of our knowledge it will be safe to regard heat as the destructive agent and to reduce the heating of all vegetables to the absolute minimum required to make them digestible.

The reduction of raw potatoes to the condition of a digestible cream would be too difficult to carry out on a large scale without the provision of some special apparatus of the type of a "Hercules press"; but small quantities of onion and spinach would be sufficiently digestible if chopped or minced into fine particles. If thoroughly mixed with a stew at the completion of cooking these vegetables should be well taken in the raw state, and would add very greatly to the antiscorbutic value of the diet.

(*c*) *The addition of some fresh vitamine-containing substance being needed germinated pulses, as suggested by Dr. Chick and Miss Hume, would provide the easiest and cheapest method of effecting this addition.*—As shown above, modern lime juice is not to be trusted as an antiscorbutic, and fresh fruit and vegetables (in the quantities available) have failed to prevent scurvy for two years in succession, but germinated haricot beans, even when fully cooked, contain at least as much vitamine as fresh raw lemon juice. Other pulses which might be germinated and would probably give as good a result are peas, beans of any variety, and unmilled lentils. It only remains to show that it would be practicable to provide these for troops in the field.

In this country germinated pulses would only be required during the winter, a season which has the disadvantage of necessitating the provision of some artificial heat to ensure germination. This disadvantage is counterbalanced by the fact that the movement of troops is lessened during the winter months.

The advantages of these dry seeds over all other forms of fruit and vegetables, both for storage and transport, are obvious. Since they double in weight and bulk and require to be kept moist when germinated, this process should be carried out as near the site of consumption as possible. In stationary trench warfare it should not be necessary to attempt germination in the actual front line, because the supply of vitamine by this method is so generous that it would suffice for preventive purposes if given every other week, or every other fortnight, when the troops were in rest.

[2] THE LANCET, 1918, ii., 735.

[3] A. Harden and S. S. Zilva: A Note on the Susceptibility of the Antiscorbutic Principle to Alkalinity, THE LANCET, Sept. 7th, 1918, p. 320.

Should, however, a battalion be compelled to stay in the front line for longer than a fortnight it would not be difficult to supply it with pulses already germinated, since at most two hundredweight (100 kg.) per day would be needed for a thousand men, and this weight represents so much food transported as well as so much vitamine.

In the case of a war of movement local conditions and temporary needs and opportunities would have to be considered as they occurred, again always keeping in mind the fact that the supply need not be continuous for preventive purposes, and that these pulses provide their full value of food as well as their supply of prophylactic vitamine.

As regards germination, the preliminary soaking for 24 hours can be done anywhere. For germination itself the essentials are moisture and protection against cold, but without the exclusion of air. The rate of germination varies with the temperature and the type of pulse. Seeds were not obtained here until too late to test them in cold weather, but, judging by the season at which peas and beans are sown in England, no cold short of definite freezing would arrest the process completely, though it would, of course, lengthen the time required for growth to take place. Hence, if facilities are lacking for keeping a supply in process of germination, the time taken must be shortened by the provision of artificial warmth.

The space required and needing to be kept warm is very small. Allowing 2 oz. per man per day, a dose which should be ample for prophylaxis, a day's supply for 1000 men could easily be accommodated in a space of 30 cubic feet. On an average of three days for soaking and germination this means that a space of 100 cubic feet would suffice to provide a continuous supply for 1000 men.

In Salonika during the three cold months, December (mean temperature 46° F.), January (mean temperature 42° F.), and February (mean temperature 45° F.), artificial warmth would be essential. For this a building or tent would be a great advantage, but failing these the necessary warmth might still be obtained by means of a hotbed anywhere within reach of fresh horse or mule manure. During November (mean temperature 52° F.) and March (mean temperature 50° F.) germination could be carried out in the open without artificial warmth, provided that some protection were given at night and during spells of bad weather. A few boxes and some old sacking would provide all the protection needed.

The beans soften so much in the process of germination that ten minutes' boiling is ample to cook them fully. If crushed or pounded they can be eaten raw, but this should rarely be necessary unless the supply ran short.

Allowing for the fact that beans are food and lemons are not, the vitamines supplied by the former are really obtained almost free of cost. Even if no allowance is made for the food value of the beans, the cost of the vitamines supplied by them would still be only 60 per cent. of the cost when supplied by lemons.

General Conclusion.

The statement of Dr. Chick and Miss Hume that germinated pulses are richly endowed with antiscorbutic vitamines is amply confirmed by the fact that germinated beans were found quite as potent as raw lemon juice in the treatment of scurvy. Their suggestion that germinated pulses should be used for the prevention of scurvy is capable of practical application, and would be the easiest and cheapest method by which to prevent the occurrence of scurvy in an army in the field.

In the case of vegetables cooked in the Army manner the destruction of vitamine which takes place cannot be ascribed to the production of alkalinity.

In conclusion, my thanks are due to Lieutenant-Colonel A. R. Greenwood, R.A.M.C., for permission to publish these cases; to Miss M. J. Ahern for careful clinical notes; and also to Quartermaster-Sergeant Andrews, R.A.M.C., for constant supervision of the germination and cooking of the beans.

DEATH OF HENRY ALBERT PATTINSON, M.R.C.S. Eng., L.R.C.P. Irel.—Mr. H. A. Pattinson died recently at Seafield House, Seaton, Devon, in his 79th year. He had practised in Seaton for more than 50 years, and had been medical officer of health for the town since the formation of the Seaton Urban Council in 1892. Expert at all games, he was prominent in founding the Seaton Cricket and Lawn Tennis Clubs and the Axe Cliff Golf Club, of which he was honorary secretary for many years.

BEER AND SCURVY.

SOME NOTES FROM HISTORY.*

BY ALICE HENDERSON SMITH.

(*From the Lister Institute of Preventive Medicine.*)

Captain Hamilton Dyke's account in THE LANCET of Oct. 19th of an outbreak of scurvy in the South African Native Labour Corps, and his demonstration of the useful place taken by kaffir beer in the diet of these natives in their homes, are very interesting in view of the use of small beer of various kinds in the Navy and other ships, and the belief that long obtained in its antiscorbutic power. During a search in the Admiralty records for information on another subject some points have come up in this connexion that it may be worth while to record briefly.

Long History of Use of Spruce-beer against Scurvy.

Beer was held for generations to have considerable value as an antiscorbutic, and was long used as such on sea-voyages. The virtue of it was not attributed solely to the various ingredients from which it was brewed but largely to the fermentation itself, and beers were made of different materials and in different ways. The early spruce-beer, which was indebted for its potency, at least in some methods of preparing it, to the fresh leaves from which it was named, has a long history. It was used by explorers at least from the time of Willem Barentz [1] and probably before that. Barentz carried on his voyages in 1594–97 casks of the "*jopen-bier*" or "*sprossen-bier*" that was then made round the Baltic with the green leaf buds or *sprossen* of the fir-tree in it, the original spruce-beer. The *sprossen* used were generally those of the spruce (*Pruce* or *Prussian*) fir (*Abies excelsa*). In this beer the green buds seem sometimes to have been added to the fermented malt, as hops are added now. Alternatively the fir was boiled in water and the infusion fermented, and since a mere infusion of spruce-tips or the fresh spruce-tips eaten as a salad have proved useful, it is probable that the original spruce-beer was of some value. Dr. Lind says [2] (in 1757):—

"A simple decoction of the tops, cones, or even bark and wood of these trees is antiscorbutic, but it becomes much more so when fermented, as in making spruce-beer. Spruce should be carried to sea; if not, the common fir-tops used for fuel should be first boiled in water and the decoction afterwards fermented with mollasses, in the common method of making spruce-beer."

He himself prescribed at Haslar, with beneficial results, a daily pint of "strong beer medicated with the most powerful antiscorbutic herbs." It was long the custom on distant voyages always to make spruce-beer on touching land, if it were possible.

But the name spruce-beer came to be applied often to beers that were entirely innocent of the fresh *sprossen*, as in the modern Dantzic spruce, whether or not the spruce flavour was introduced. The essential element, of course, from the point of view of scurvy, was the freshness of the vegetable ingredient, and, as has happened in the history of other antiscorbutics, the belief in the value of the drink persisted after the elimination of the element on which that value depended. We find later an Arctic officer stating that spruce-beer was brewed on board his ship when she was in the ice several degrees of latitude beyond the highest at which the fir grows. This beer was sugar or malt beer, flavoured with "essence of spruce."

Value of Sweetwort.

The value of fresh germinated barley has been shown anew recently by Fürst,[3] and the actual experience of its use seems to suggest that malt which is not "highly dried," as in the modern manner, probably retains much of its potency. Even in a simple brewing process the beer may

* Companion papers entitled (1) The Relative Content of Antiscorbutic Principle in Limes and Lemons together with Some New Facts and Some Old Observations Concerning the Value of "Lime Juice" in the Prevention of Scurvy, (A) *Experimental Inquiry*, by Harriette Chick, E. Margaret Hume, and Ruth F. Skelton, (B) *Historical Inquiry*, by Alice Henderson Smith, and (2) An Investigation of the Antiscorbutic Value of the Raw Juices of Root Vegetables, with a View to their Adoption as an Adjunct to the Dietary of Infants, by Harriette Chick and Mabel Rhodes, appeared in THE LANCET of Nov. 30th, 1918 (p. 735), and Dec. 7th, 1918 (p. 774), respectively.

[3] Fürst: Zeitschrift f. Hygiene, 1912, vol. lxxii.

still keep some of the barley's virtue, apart from any that the fermentation or added ingredients may give it. Captain Dyke shows that this is the case with the germinated millet of the Kaffirs, and malt beer and an infusion of malt called "sweetwort" were used, with a profound belief and a good deal of evidence in their favour.

Sweetwort was proposed for use in the Navy by Dr. David McBryde in 1762. It was an infusion prepared by pouring boiling water over malt and allowing it to stand for three or four hours, after which it must be used at once. It is, so far, similar to the kaffir beer, but the sweetwort was not fermented; and, of course, the African drink has this advantage, that the grain is germinated as it is required and used absolutely fresh, whereas the sweetwort was made from malt carried to sea. Preliminary trials of Dr. McBryde's receipt at the Royal Hospital, Plymouth, were unfortunate owing to his demanding for its best demonstration the exclusion of all fresh meat and vegetables from the patient's diet. Naturally it was with great reluctance that the patients submitted, and when a man died of scurvy under the treatment the experiment was stopped. It was then suggested by the Sick and Wounded Board of the Admiralty for use on board ship, where fresh food was not available, and it was ordered to be carried to sea, but the peace of 1763 put an end to opportunities for testing it. It was as an experiment still, in 1770, that "barrels of well-dried malt" were ordered to be put on board two of H.M. ships for trial in scurvy cases, and in the following year an "inspissated juice of malt" was tried. Captain Cook seems to have had both of these when he sailed in 1772. In this classical example of a long voyage without serious loss from scurvy in days when great suffering and loss from the disease were the rule, sweetwort was the prophylactic to which he attributed much of the credit of the immunity. After his ship, the *Resolution*, had been at sea continuously from Nov. 22nd, 1772, until March 26th, 1773, we read [4]:—

"After such a long continuance at sea in a high southern latitude, it is but reasonable to think that many of the people must be ill of the scurvy. The contrary, however, happened. Sweetwort had been given to such as were scorbutic. This had so far the desired effect, that they had only one man on board that could be called very ill of this disease, occasioned chiefly by a bad habit of body and a complication of other disorders."

And this sweetwort is described [4] as "one of the best antiscorbutic sea-medicines then discovered when used in time." Other antiscorbutics that Captain Cook had with him were saurkraut and a "rob" or essence of lemons and oranges. He also brewed malt or spruce-beer whenever opportunity offered.

Another explicit statement of the value of the sweetwort occurs in a letter [5] from Admiral Graves to the Victualling Board of the Admiralty in 1794, in which he says:—

"On the American voyage of the *London* essence of wort [the same malt infusion apparently, from the context] had been given, with such vegetable acids as the surgeon had. Scurvy gradually gave way, and they sent only four to hospital instead of thirty or forty, as other ships did at New York."

It was among several antiscorbutics in constant requisition in the Navy, until they were abolished on the introduction of lemon juice.

Further Experience of Malt Liquor as an Antiscorbutic.

Dr. James Lind [6] says that beer, wine, and other fermented liquors are all antiscorbutic. Sir Gilbert Blane [7] held the same opinion, and, when speaking of the "extremely wholesome and antiscorbutic" nature of malt liquor, he says:—

"The common quantity of small beer allowed (in the Navy) is so liberal that few men make use of their whole allowance; and there is no objection to the constant use of it except that it is apt to spoil in the course of a few weeks, and that upon foreign stations the stock can seldom be renewed. One of the greatest improvements that could be made in the victualling of the Navy would be the introduction of porter, which can be preserved in any climate for any length of time that may be necessary."

As a matter of fact, porter was sometimes refused, when asked for for the sick, on the ground of expense, wine being given instead. He goes on:—

"I was furnished by Dr. Clephane, physician to the Fleet at New York, with the following fact. In the beginning of the war two storeships called *Tortoise* and *Grampus* sailed for America under convoy of *Daedalus*, frigate. *Grampus* happened to be supplied with sufficient quantities of porter to serve the whole passage, which proved very long. The other two ships were furnished with the common allowance of spirits. The weather being unfavourable the passage drew out to fourteen weeks, and upon their arrival at New York the *Daedalus* sent to hospital a hundred and twelve men, the *Tortoise* sixty-two, the greater part of whom were in the last stage of the scurvy. The *Grampus* sent only thirteen, none of whom had the scurvy."

Sir Gilbert believed, also, in the virtue of spruce-beer, and says that as the fir "seems to be more medicinal and antiscorbutic than hops, it is therefore perhaps preferable to malt liquor." Beer was issued in the Navy in his time at the rate of a gallon per head per day so long as the supply taken out lasted; but this was never for more than about a fortnight, after which grog or wine was given, the allowance of wine being a pint a day. For foreign service beer was not supplied at all.

When the war with Spain, in 1796, sent up the price of lemon juice by cutting off a source of supplies, the Sick and Wounded Board wrote to the Lords Commissioners that "though they do not consider strong beer a substitute for lime juice and sugar for scurvy, yet as it is conducive, they recommend" that the experiment be made of substituting it on some ships.

Beer, then, had a solid reputation as an antiscorbutic, although by the beginning of last century the first place was, of course, given to lemon juice. When the end of the long wars permitted the renewal of the search for the North-West passage in 1818, malt and yeast were taken on the exploring ships and small beer was brewed on board. Sir Edward Parry himself attributed great importance to it, and other explorers of his time concur in this opinion. Malt was carried, too, by the whaling vessels, whose business took them farther into the North than any others except the explorers, and who were, like them, liable to be detained in the ice for long periods. When Sir John Franklin went out in 1845, and was followed later by many ships sent out to seek him, a brewing apparatus was carried and beer was brewed on board these ships. But they also carried Allsopp's pale ale in casks and used it while it lasted, generally through the first winter. The belief in beer was firmly established, and it was always issued at once to men on the sick-list on these expeditions. It was also issued on some ships as an extra safeguard against scurvy for some time before sledging parties went out; and by Sir Leopold McClintock it was actually issued at times as an alternative to lemon juice.

Elimination of Antiscorbutic Element.

But by the time the Franklin Search ships went out the malt used was "high-dried, kilned malt."[8] Again the essential element is removed without its importance being observed, and the traditional belief now pertains to a beer from which the antiscorbutic value of the germinated malt has been removed unwittingly by the improvement of the malting processes. This alters the whole question and throws on to other elements in the drink any dietetic value it may have possessed. Moreover, in view of the unstable nature of the protective element it is probable that, whatever the malt used, any antiscorbutic value that beer may have must be greater in a freshly brewed beer, consumed immediately, than in ales made for export and kept for many months before they are used. The tradition was strong, however, and the officers of the Franklin Search ships believed in their beer; many of them speak of it as a wholesome and suitable beverage for Arctic service, and attribute to it something of the good health and freedom from scurvy of their men. In so far as it was substituted for rum, it could be only good, but when tested as an antiscorbutic it fails. The British ships were at this time fortified effectively against scurvy with lemon juice, but the American ships of the Grinnell Expeditions [9] that took part in the search for Franklin did not use lemon juice; they relied principally upon raw potatoes and molasses, but beer brewed on board ship was reckoned a considerable part of their defence. The first Grinnell ships left the States in May, 1850, and scurvy began to show on board of them so early as September. There is surely little practical antiscurvy value in a regimen that permits the onset of scurvy in so short a time, and that notwithstanding the fact that the ships had a certain amount of fresh meat in summer. Dr. Kane, who was medical officer of the first Grinnell Expedition, was commander of the second, and went out

[8] Messrs. Samuel Allsopp and Sons have kindly given me explicit data about the beer supplied by them to these ships.
[9] "U.S. Grinnell Expedition in Search of Sir John Franklin." Dr. Elias Kent Kane, 1851; Arctic Exploration: the Second Grinnell Expedition, Dr. Elias Kent Kane, 1856.

again in 1853. In his long wrestling with scurvy he spent his resources, apparently out of all proportion to the results, to produce any sort of fermented drink for his men; and his laborious achievement of a sort of beer when there were only three men, himself included, of the ship's company able to move from their bunks, argues a great faith in its value. But there is nothing to show that it justified his faith. All his ingenuity may possibly have delayed the onset and progress of the disease, but his men were in the last stages of scurvy and it was only their occasional supplies of fresh meat that saved them.

At its best, under the most favourable conditions, it has never been claimed that beer is a complete protection from scurvy over any extended period of time; and even in Cook's time his beer and his infusion of malt did not alone confer invulnerability. But (before lemon juice removed the need of it) malt preparations do seem to have given a very considerable measure of protection when methods of malting and brewing were simple. Later, as a nourishing drink, and as a substitute for spirits, beer still had value for the seaman on Arctic service; but with the elaborating and perfecting of malting and brewing processes, the antiscorbutic element seems to have been largely if not completely eliminated. Thus the conclusion drawn by Harden and Zilva [10] from their recent experiments with beer made from kilned malt is confirmed by the history of its failure in Arctic experience. But Captain Dyke's account confirms and justifies the belief in the beer used by earlier generations in the Navy, a hundred and twenty years ago.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

PRE-OPERATIVE X RAY DEMONSTRATION OF SILENT INTRATHORACIC METASTASES OF MALIGNANT DISEASE.

BY C. HAMILTON WHITEFORD, M.R.C.S., L.R.C.P.

THERE are probably few surgeons who, after having removed a malignant growth with its lymphatic area, have not experienced the disappointment of seeing the patient rapidly die from intrathoracic metastases, while the operation area remained free from recurrence. In not a few of these cases the symptoms of intratboracic involvement appear so soon that there can be no reasonable doubt that the secondary growths were actually present at the time of the operation. Secondary deposits within the thorax are often "silent"—i.e., may exist for a long time and reach a considerable size before giving a distinctive clinical picture. Radiography is in many cases able to demonstrate the existence of these metastases while still silent. Of this the following case is an example.

A stout multipara, aged 60 years, was seen by the writer last spring. The right breast contained a cancerous mass, the size of a lawn-tennis ball, which had invaded the skin surrounding the nipple, but had not yet ulcerated. The breast was freely movable on the chest wall. No glandular involvement could be felt. Clinically the thoracic contents appeared normal. Except for a somewhat feeble pulse there was no obvious reason why a radical operation should not give a chance of cure, provided that radiography showed no intrathoracic metastasis. The skiagram, however, showed, in both sides of the chest, masses of growth, which appeared as shadows, 5 inches in vertical extent, to the right and left of the sternum and pericardium. The husband was informed of the impossibility of a cure by operation, but was advised to sanction a simple removal of the breast in order to prevent the sepsis which would occur as soon as the involved skin gave way.

The breast was removed, and 14 days later the patient left the nursing home. The pathologist reported that the growth was an alveolar carcinoma with very little connective tissue. Three weeks after operation a slight cough developed, but subsided under treatment. Six weeks after operation dyspnœa commenced and the cough returned, with crepitations in both lungs, death occurring three months after removal of the breast.

In nearly every form of malignant disease the thoracic contents are a possible site of metastases which for a time may cause no symptoms. The presence or absence of such metastases cannot be decided by a consideration of either the size, duration, or position of the primary growth. Further, the metastases frequently cannot be detected by ordinary clinical methods.

Radiologists are now usually able to demonstrate the presence of secondary malignant deposits within the chest. There is no reason why the radiographic examinations should not include regions other than the thorax in which deep-seated silent metastases are prone to occur.

The principle of employing routine pre-operative radiography in those varieties of malignant disease, both sarcoma and carcinoma, which are liable to cause intrathoracic metastases is relatively new, and at present is but little acted upon. Its importance for the prevention of useless operations is obvious. The principle is deserving of wide recognition and application.

The results of its adoption in the surgery of malignant disease may be expected to include: 1. A diminution in the number of radical operations performed on cases in which the disease has, prior to operation, produced inoperable metastases, and this elimination of incurable cases will, as time goes on, result in a higher percentage of cures among the cases on which radical operations are performed. 2. A decrease in the number of palliative operations, because many patients decline any form of operation unless the surgeon is able to hold out a definite possibility that the operation may result in cure.

TOTAL EXCISION OF THE URINARY BLADDER.

BY JOHN C. JEFFERSON, F.R.C.S. ENG.,
HONORARY SURGEON, ROCHDALE INFIRMARY.

THE following record gives an account of a case of total excision of the urinary bladder in a woman for advanced epithelioma of the urethra.

A married woman, aged 60, admitted to Rochdale Infirmary, stated that three months before she had noticed pain on micturition and difficulty in emptying the bladder, these symptoms gradually becoming worse. About two weeks before admission incontinence took the place of retention. An advanced epithelioma of the urethra was found. I am of the opinion that it originated within the urethra, as the greater part was inside the urethral orifice and not actually about it. Further, though the growth had invaded the sphincter vesicæ, causing incontinence, it had not become attached to the pubic rami. The inguinal glands on the left side were enlarged, but freely movable. The patient was in good condition. Some urine obtained by taking catheter specimens was not foul, though it contained pus, and it improved considerably under treatment. As the patient was in a very miserable condition owing to the constant dribbling away of the urine, I decided to transplant the ureters with their vesical orifices into the colon, to remove the bladder and urethra completely, and at a subsequent operation to remove the inguinal glands.

On March 4th, 1918, with patient in high Trendelenburg position, I opened the abdomen in the middle line, the incision extending from pubis to umbilicus. The intestines were thoroughly packed off with gauze and the wound edges protected with tetras. A transverse incision was made through the vesico-uterine fold of peritoneum and the bladder separated from the cervix uteri and vagina. The ureters were readily distinguished and isolated for not more than ¼ inch from their entry into the bladder, a stout loop of silk passed beneath each facilitating handling. The peritoneum on the superior aspect of the bladder was peeled off and the viscus freed on all sides until the pelvic floor was reached. The bladder was opened and the ureteric orifices, with a small circle of mucous membrane around each, excised.

The pelvic colon, which, fortunately, had a long mesentery, was next brought down and each ureter transplanted into it separately, as follows. A linen thread stay suture was passed through the mucous membrane around the ureteric orifice. A small incision was next made into the lumen of the colon through the anterior muscular band. Both free ends of the thread were now passed through the eye of a long curved intestinal needle, the needle passed into the lumen of the bowel through the incision and out again through its walls about 1 inch from the point of entry. By drawing on the thread the ureter was then pulled well inside the bowel and retained there while the aperture was closed around it and the terminal free part of the ureter enfolded in the bowel wall with Lembert sutures. The stay suture was then cut and removed. By this means the

ureter was drawn through a considerably smaller aperture in the bowel than otherwise would have been possible, and one was enabled to work with a shorter length of isolated ureter.

The transverse incision through the peritoneum of the utero-vesical fold was now sutured around the portion of pelvic colon which had been brought down and the abdomen closed without drainage. The patient was placed in the lithotomy position and the removal of the bladder, together with the urethra and the lower part of the anterior wall of the vagina, rapidly completed. A large drainage-tube was inserted into the space left.

The patient bore the operation remarkably well and, with the exception of a little bronchitis, made an uninterrupted recovery. Thirty days after the first operation I wished to remove the inguinal glands on the left side, now considerably enlarged but still freely movable. The patient, however, insisted on returning home for ten days. I reluctantly agreed to this, but owing to an attack of pleurisy she did not return to hospital until August 5th. By this time the glands were so extensively invaded that it was impossible to remove them completely.

The patient has fair control over her rectum, though the bowels are moved on an average five times during the day and twice during the night. There have been no symptoms of ascending infection of the ureters and kidneys. This I consider due to the fact that the whole orifices of the ureters into the bladder, and not the ureters only, were transplanted. There has been no recurrence of growth in the vagina.

I cannot help thinking that had the patient consented to earlier removal of the glands the result would have been much more fortunate. The operation itself was tedious but not difficult. The transplantation of the ureters in the depths of the pelvis was a delicate procedure, requiring care and patience, though it was much facilitated by the stay suture.

ROYAL SOCIETY OF MEDICINE.

SECTION OF PATHOLOGY.

Discussion on the Pathology of Gas Gangrene.

A MEETING of this section was held on Dec. 3rd, Professor W. BULLOCH, the President, being in the chair, when a discussion took place on the Pathology of Gas Gangrene.

Incidence and Bacteriology.

Dr. JAMES MCINTOSH, speaking on researches on the bacteriology of the condition, said that gas gangrene appeared to have been almost unrecognised previous to the Crimean campaign, when it was described under the name of "gangrène foudroyante." Later it seemed to have been confused with various inflammatory conditions, such as hospital gangrene and erysipelas.

On the Western front during the present war its incidence had varied from time to time according to the battle area and the efficiency with which the wounded were dealt, so that reliable statistics were difficult to compile. The incidence among British troops, declining since the early months of the war, has lately only been about 1 per cent. during the most active operations. But even this meant a good deal when many thousands of wounded were being dealt with.

The researches of Pasteur, Koch, Welch, and others showed that the exciting agents were anaerobic bacteria, which were present in all cultivated soils, and thus contaminated the wounds at the time of their infliction. The injured tissues seemed to provide a suitable nidus for the growth of these bacteria, as within a few hours of the infliction of the wound gas gangrene might have already developed. Previous to the outbreak of hostilities Breiger and Ehrlich had shown that the bacillus of malignant œdema (*Vibrion septique*) was capable of infecting man, whilst Welch and Fraenkel demonstrated that the *Bacillus aerogenes capsulatus* had similar pathogenic properties. There was no doubt as to the cause of gas gangrene, but there was considerable diversity of opinion with regard to the most prevalent type, and to the chief features of the types isolated. This was due to (1) the difficulty of isolating many of these anaerobes and of obtaining pure cultures; and (2) the methods of isolation employed in many instances being such as would tend to bring out the saprophytic forms in preference to the more delicate pathogenic varieties. As an indication of the relative incidence of the different anaerobic bacteria met with in cases of gas gangrene, Dr. McIntosh gave some results compiled from his own observations made on behalf of the Medical Research Committee. In a series of 41 cases from 1914–17, *B. welchii* occurred in 43·9 per cent., *B. sporogenes* (types 1 and 2) in 29·2 per cent., *Vibrion septique* in 19·5 per cent., terminal oval sporing bacilli in 17 per cent.; and of undifferentiated types, type No. 13 in 7·3 per cent., type No. 18 in 4·8 per cent., and type No. 19 in 4·8 per cent. In a second series of 52 cases during 1918, *B. welchii* occurred in 67·3 per cent., *B. sporogenes* in 38·7 per cent., *Vibrion septique* in 16·3 per cent., *B. œdematiens* in 4 per cent., terminal oval spores in 8·1 per cent., and *B. pseudo-tetanus* in 2 per cent.

Results of Investigations on Causation and Treatment.

Major J. W. MCNEE laid emphasis on the large number of men who, in the first two years of the war, lost their lives or their limbs from gas gangrene. Owing to the early onset of the complication, which usually developed within the first 48 hours after injury, many cases never reached the base, so that for many workers there could be no clear mental picture of the fulminating cases. The earliest development of gas gangrene which he had seen occurred 3½ hours after receipt of the wound, and it was often well established in 10 hours. The rapidity of spread was far in excess of any microbic infection of which he knew, and half an hour's delay in operation might make all the difference between life and death. Gas gangrene reached its height during 1915, and at this time meant the death of the patient or, at best, his survival after amputation of a limb.

In 1916, in close association with Surgeon-General Cuthbert Wallace, deliberate work was begun in the First Army on the pathology of the condition, especially by Captain Shaw Dunn and himself. This work arose out of various clinical observations. It was insisted on by Wallace and Kenneth Taylor that gas gangrene was essentially a disease of muscle, and never arose when muscle injury could be excluded. It was also observed that in early cases of gas gangrene single muscles of a group were often involved whilst neighbouring ones escaped. These observations had special reference to gas gangrene spreading in a limb with an intact blood-supply, and the method of spread in such cases formed their first line of research. It was realised that cases of what came to be known as *group* gangrene were in a different category as regards spread. In them a large blood-vessel was always divided—e.g., the popliteal—and gangrene of gaseous type commenced in all the muscles of the group simultaneously. The onset of gangrene in such devascularised segments of limbs was seen to be analogous to invasion of the warm tissues after death, such as occurs in hot weather. Sections illustrating the spread of gas gangrene in living muscle with an intact blood-supply were shown. In their account of their work, which has already been published in full, great emphasis was laid on the *spreading edge of the gangrene*, a histological study of which gave the clue to the method of spread. The essential factor in the spread was the passing up of a fluid substance in the sheaths of the muscle fibres, causing death and coagulation necrosis of the muscle fibres. In the muscle fibres so killed off an invasion by the anaerobic bacilli at once took place, the muscle sugar being split to give the characteristic evolution of gas. It was not until Bull's work on *B. welchii* toxin was published that the full truth was known. They called the spreading edge where the muscle had just been killed off the "pre-gas" zone of gangrene. Experiments on rabbits showed that if the organisms freshly isolated from a human case were injected intramuscularly no spreading gas gangrene followed unless the muscle was first extensively injured or blood clot was produced.

In wounds of this war, in contrast to those of other wars, all the necessary conditions for the origin of gas gangrene were provided. This war had been fought on a heavily manured soil, saturated with the anaerobic bacilli derived from animal manure. We had had the composite bullet, which breaks up readily, and we had had the short-range warfare of the trenches, so that

when a bone was struck it shattered into fragments, tearing up the muscles around. Moreover, we had in this war as never before all the varieties of jagged and irregular missiles, often carrying in cloth along with them, derived from the bursting of shells and bombs of every kind. As a consequence every wound in this war was accompanied by great laceration and damage to muscle, while practically every wound was infected with anaerobes from the start, by clothing, dirt, &c.

During 1916 and 1917 the dead and damaged muscle, in which alone gas gangrene could commence, was removed by operation, and for the treatment of early cases, knowing the method of spread, single infected muscles or parts of them could often be removed in time to arrest the disease, while the limb as a whole was saved. It was obviously necessary that operations should be carried out at the earliest moment possible after wounding, and for this reason the casualty clearing stations were pushed as far up as possible. The results of these measures were very soon obvious. Whereas during the previous year in one C.C.S. the gas gangrene incidence ranged around 8 per cent. in quiet periods, and was known to be almost double in periods of activity when the wounded came back slowly owing to numbers, with the new methods of wound treatment the incidence of gas gangrene fell towards the end of 1917 to just below 2 per cent. This was before any serum therapy had been thought of, and before Bull had announced the discovery of *B. welchii* toxin. During the end of 1917 and the present year the majority of cases of gas gangrene had occurred amongst men who had either had to be brought to the casualty clearing stations over long distances and bad roads, or who had arrived in a pulseless condition from shock or hæmorrhage, or both, and consequently unfit for operation. When gas gangrene is developing the blood pressure rises at first, and the medical officer, unless he is on his guard, may think that the man is recovering.

Speaking of the bacteriology of the condition, he said that in the acute spreading gangrenes of limbs *B. welchii* was evidently the chief organism concerned. It could be found in great numbers, and in almost pure culture, close up to the spreading edge of the gangrene. Such rapidly spreading gangrenes exhibited an intense toxæmia in the later stages, but the organism seldom invaded the blood stream except just before death. During the past year, with the *B. welchii* infections well controlled by surgical methods, other forms of gas gangrene associated more with toxæmia than rapid spread in muscle had consequently come into more prominence. They were of intense toxæmic type, and gave positive blood cultures of a motile anaerobe, the *Vibrion septique*. In his own army area such cases had been rare. With regard to the third great toxin-producing anaerobe (*B. œdematiens*) isolated in cases of gas gangrene by Weinberg and Seguin, he had only seen two or three cases where its presence as the main factor in etiology was suspected. The epoch of serum therapy dated from the time when Bull, working in the Rockefeller Institute, found an exotoxin produced by *B. welchii*, and by the injection of this produced an antitoxic serum. In his work in France he met with many disappointments, but he came at a time when the *B. welchii* infections were already well controlled by surgical methods, and a large proportion of the men on whom he had to make his tests were those developing gas gangrene while lying in a state of shock in the resuscitation wards. The results were encouraging, however, from the way in which some of the toxæmic cases were controlled. In other cases in which the toxæmic symptoms were unchecked, the cultivation of *V. septique* from the blood showed clearly that this organism must be considered in any future serum developments. This year a fairly extensive prophylactic trial was made in three divisions of the First Army with an antitetanic serum containing also anti-substances to *B. welchii*, being controlled by a comparison with neighbouring divisions in the army; the serum was injected as soon as possible after wounding, generally within 3–5 hours. There was no reduction in the case incidence in the C.C.S. zone as compared with control divisions, but the figures seemed to show a reduction in case mortality at the bases. In connexion with the sera used curatively, the cases developing gas gangrene were mostly men in a condition of shock, or in whom operation had been much delayed by long travelling over bad roads. The results were therefore difficult to appraise, and were certainly not dramatic.

Professor M. WEINBERG, the PRESIDENT, Major A. W. M. ELLIS, and Captain H. P. M. HENRY also spoke.

SECTION OF SURGERY.

The Closure of Cavities in Bones.

A MEETING of this section was held on Dec. 4th, Sir JOHN BLAND-SUTTON, the President, being in the chair.

Lieutenant-Colonel PERCY SARGENT read a paper on the Closure of Cavities in Bones.

Processes of Repair in Bone.

He said that the processes of repair in bone differed in no way from those which occurred in other vascular tissues; but they were modified by its peculiar and complex structure. Tissues healed well or ill according to their vascularity, and so cancellous bone was more adapted for recovery than compact bone, and the abnormally dense bone which resulted from chronic inflammation was a great handicap. Another factor which retarded the healing of cavities in bones was the fact that the walls were not collapsible. It was necessary for the walls to be approximated until the granulations which covered them were able to coalesce. Two processes combined to bring about the coalescence of the granulations covering the wall of a cavity: (1) the falling together of the adjacent structures, and (2) the process of contraction which was always associated with the development of granulations. In the case of a bone cavity, it was clear that its walls could not fall together from the pressure of the surrounding structures, nor could they be drawn together by the contraction of the developing fibrous tissue. Colonel Sargent then described a case in which a cavity had been in existence for 16 years after a two-year-old sequestrum had been removed from it, the cavity measuring 3 inches in length, the sequestrum 4 inches. It had taken 16 years for the cavity to be reduced in length 1 inch. We might therefore suppose that the process of filling up a bony cavity, by the growth of new tissue upon its walls, whilst it might slow down, did not necessarily come to an end completely; that, although in theory a cavity of any size might ultimately be obliterated in this manner, the process would be so slow as to need longer than the life-time of the patient—a life-time apt to be shortened by chronic septic absorption, or by any of the accidents which threatened a patient who bore a source of chronic suppuration.

Methods of Filling Cavities in Bone.

The problem of filling up old bone cavities had been attacked in different ways:

1. In 1886 Schede recommended a procedure based upon the process of "healing by blood clot." His method was as follows: An Esmarch's bandage having been applied to the limb, the cavity was prepared with the greatest care so as to render it as clean as possible, and the wound was closed. On removal of the bandage the cavity would fill with blood, which, the wound being relatively aseptic, would become organised into, or replaced by, fibrous tissue.

2. Pieces of sponge had been packed into the cavity, in the expectation that such tissue would form a framework for the growth of granulations.

3. Neuber's method consisted in laying open the cavity by removal of one of its bony walls and inverting flaps of skin into the groove so formed, the flaps being secured in position by means of nails.

4. Senn advocated the use of decalcified bone which had been prepared by soaking in 1 in 500 sublimate alcohol. The cavity, carefully prepared, and rendered as aseptic as possible, was to be firmly packed with chips of this decalcified bone.

5. A method of plugging bone cavities with a paste compounded of iodoform, spermaceti, and oil of sesame, was described by Moorhof and Seymour Jones in 1905. The cavity to be treated was to be cleaned, dried, and filled up with this paste, which was stated gradually to disappear, and to be replaced by bone. Moorhof claimed to have treated 220 cases in this manner without a failure. Both the last described method and that of Schede demand conditions which must rarely be attainable. "It is an absolute *sine qua non*," wrote Moorhof and Jones, "that the walls of the cavity to be plugged should contain no diseased tissue, and should be perfectly aseptic."

6. Another method of filling the bony cavities was described by Hollander. The cavity was carefully cleansed and prepared, and was then filled up by pouring melted human fat into it. The fat so obtained at operation from lipomata or omentum was freed from connective tissue and melted in a water-bath. It was claimed that in some instances healing by first intention occurred, but that in the majority the wound took about three weeks to heal. It was further stated that the scar, instead of being adherent to the bone and depressed, was freely movable and flush with the surface.

7. Professor A. Broca said that the persistent sinus was due to the persistence of osteitis and the existence of a suppurating cavity, the obliteration of which should be at least as much the object of operation as the removal of sequestra. Broca's radical operation aimed at the obliteration of the cavity by the falling in of the soft parts. The bone was freely exposed through an incision situated at the most convenient place as regards its anatomical relationships; existing sinuses at a distance from the site of election were ignored. The cavity was converted into an open trough or gutter by the free removal of one of its walls. Any sequestra and all diseased tissue were removed, special care being taken to follow up all recesses and diverticula from the main cavity. The overlying soft parts were then encouraged to sink into and gradually to obliterate the resultant cavity.

Technique of Modification of Broca's Operation.

The method which the speaker wished to advocate was a modification of Broca's operation, and one which he thought in most cases offered certain definite advantages. It might be called that of muscle-grafting, to which might be prefixed the term (as Professor Shattock suggested) "continuous"—in contradistinction to "discontinuous"—grafting, seeing that the slip of muscle used to fill the cavity was not completely separated but retained its continuity with the main mass. Before undertaking the operation the bone was carefully examined by means of stereoscopic radiograms.

The technique of the procedure was as follows. No tourniquet was employed. The use of a tourniquet certainly rendered certain stages of the operation more easy, but the subsequent oozing was a great drawback. Hæmorrhage was easily kept under control by the frequent application of large pieces of gauze wrung out in very hot saline. As a rule, the operative field could be kept dry by this means. Further, it was easier to judge of the condition of a bone which bleeds under the curette than of one which was temporarily deprived of its blood-supply. Again, as these operations consumed a considerable amount of time, the total deprivation of blood for an hour or more of skin whose nutrition was already impaired by scarring might result in subsequent sloughing. One of the most essential points in the operation was to secure a sufficiently thorough exposure of bone both above and below the site of the cavity which was to be attacked. The surgeon must see exactly what he was doing in every part of the operative field, and not trust to the curette for discovering hidden recesses. He usually began by a fairly wide excision of the wall of the sinus which leads down to the bony cavity. When more than one sinus existed he selected the one which was most conveniently situated and which gave the easiest and most direct access to the bone, having regard to the anatomy of the structures in the neighbourhood. Any other sinuses might or might not be dealt with, according to their situation and the density of their walls. The periosteum was next incised to the extent of the whole length of the wound and stripped from the bone so as to bare it completely, not only at the actual site of the cavity, but for some distance both above and below. At this stage it was convenient to employ Lane's bone levers instead of the ordinary retractors so as to bring the bone into prominence by depressing the soft parts; they were inserted between the periosteum and the bone. Before attacking the bone it was necessary to pack it off by means of gauze pads, partly to prevent soiling of the wound generally, but particularly to prevent fragments of bone getting lost amongst the soft parts and being accidentally left behind. This was most important, more than one of his own failures being due to the leaving behind of bone chips. That part of the operation which consisted in preparing the cavity for the graft was entirely subperiosteal. The bone so exposed could be thoroughly examined, and a decision made as to which wall of the cavity could best be spared from the point of view of strength of the bone. Other things being equal, that aspect of the bone was selected for removal which was most conveniently related to such overlying muscles as could best be employed for filling the cavity. These points being decided, the cavity in the bone was fully opened up by means of a chisel and mallet until every part of it could be thoroughly explored. All granulation tissue and dead or carious bone must be removed, and all recesses carefully followed up and cleansed. The cavity was next washed out with hot saline solution and plugged tightly with gauze. This completed the first stage of the operation.

The second stage was not commenced until all soiled packing had been removed, the towels changed, the instruments re-sterilised, and the surgeon's and assistant's gloves had been changed. From this point onwards the operation must be regarded as an aseptic procedure. The wound, of course, was not free from bacteria, but their number had been so reduced that the tissues could deal with the remainder. The best method of filling the cavity with muscle was different in every case: what one must do was to fashion from the most conveniently situated mass of muscle a thick, broad-pedicled flap of approximately the same size as the cavity. It was a plastic operation based upon the same principles as those which govern plastic operations in general, and the main point to be kept in mind was to secure an adequate blood-supply to the transplanted muscle. The muscle graft was now pushed into the cavity and pressed home firmly; it readily adhered to the bone. A few stitches of catgut might be required to bring together the overlying muscles and to assist in keeping the graft in position. The skin was loosely sutured and the subsequent escape of exudate was provided for by means of rolls of rubber sheeting inserted in convenient parts of the wound. It was important to place one such drain in the space from which the muscle graft had been cut. These drains were usually removed at the end of 48 hours. The limb was splinted in such a way as to relax the parent muscle.

In some cases these wounds had healed practically by first intention, but there was often a considerable reaction, which might last for several days, the temperature being raised to 101° or higher and the wound discharging a quantity of exudate, which was sometimes thin and watery and sometimes frankly purulent. In one or two instances severe suppuration had occurred, but the wounds had, nevertheless, eventually healed soundly.

Advantages of the Muscle-graft Method

The advantage of the muscle graft over the method of Broca was that less bone need be removed, and it was not necessary to convert the whole cavity into an open gutter. Hence the bone need not be weakened to the same extent. (Broca spoke of fractures having occurred during his operation.) Further, the cavity often extended into the articular end of a bone, in which case it could not be converted into an open trough in its whole extent. The obliteration of the cavity by the falling in, or pressing in, of the overlying soft parts might take some time, and might fail to be complete; by means of muscle grafting we got an immediate and entire filling up of the space. In contrast with the other materials which had been used, we had in muscle a living vascular tissue which might be presumed to furnish cells and fluids capable of completing the removal of such micro-organisms as might remain. It was possible that, in parts at least, union between the raw bone and raw muscle might occur by first intention, or the bone and muscle might each become covered with granulations which might subsequently unite. In either case the respective blood-vessels of bone and muscle coalesced, so that an additional supply of blood was brought to the bone. We had no evidence that bone formation occurred in the graft, but it might conceivably occur should the parts concerned be not strictly aseptic, and the graft become the seat of a chronic myositis. The graft retained its connexion with the parent muscle and might take with it a nerve-supply, in part at least. It need not cease to function if the arrangement were such as merely to make the transplanted slip arise from, or shift its insertion into, another part of the bone. The fate of the graft was a matter of subsidiary importance; for if the procedure had successfully obliterated the cavity, its real object had been attained—namely, sound and final healing. Whether ossification ultimately would take place

was immaterial from the point of view of strength, for, as the patient used the limb, and so subjected the bone to strains and stresses, compensatory overgrowth occurred. This was well exemplified in a radiogram taken by Captain Keen.

Discussion.

Captain B. S. SIMMONDS spoke of the work he had carried out with Colonel Sargent and Major Oswald Shields at Tooting Military Hospital in dealing with gunshot fractures which were unhealed, owing to the presence of septic tunnels and cavities in bone. Their object had been in all cases (1) to expose freely by periosteal resection the whole area of the injury to the bone; (2) to open up thoroughly the cavity or tunnel so that its whole extent could be explored; (3) to remove all sequestra and diseased bone, and the fibrous tissue and granulations lining the cavity or tunnel; and (4) to arrange for soft parts to fill up the cleaned cavity completely. He thought that every case should be treated on its merits without one method exclusively being adopted. Many cases of tunnel and cavity which could, without removal of too much bone, be converted into a shallow cavity could be cured by Broca's method; but other cases, such as cavities involving the condyles of the femur, and cavities in which removal of sufficient bone would endanger the function of the limb, were best treated by the muscle graft.

Captain Z. MENNELL said that during the past year he had performed this operation on about 27 cases, 23 of which could be traced. He wished to emphasise certain points: 1. The need for complete excision of the sinus which leads to the bone cavity and of the surrounding scar tissue. It was essential that the incision should run through healthy skin, so that the stitches need not pass through scar tissue or sustain any tension. 2. The careful packing off of the wound so as to avoid bone chips being overlooked. 3. The muscle tissue used as a graft must be muscle tissue only, without tendon or fascia attached to the surface which comes into contact with the raw bone surface. The graft must have a good blood-supply and be free at one end. 4. Efficient drainage of the cavity from which the muscle has been taken through a separate wound in the most dependent position possible. 5. The need for firm pressure over the muscle in the cavity when the dressing was applied. 6. Careful examination of each case for any interference of the blood-supply to the limb. Referring to the after-effects, he said that there was very considerable oozing. This need not cause alarm, and only necessitated packing the wound outside the original dressing and perhaps a firm bandage in addition. There was often considerable reaction and sometimes, in addition to constitutional symptoms, such as fever, an apparent severe local infection. This only lasted a short time, and if there was sufficient drainage no ill-effects appeared.

Mr. C. H. FAGGE and Major OSWALD SHIELDS also spoke.

Major JOHN R. LEE read a paper on Compound Fractures of the Femur in its Upper Third and demonstrated his pelvis-femur splint, and also a splint for fractures of the upper extremities. The paper will be published in a later issue of THE LANCET.

SECTION OF ANÆSTHETICS.

The Present Position of Spinal Anæsthesia.

A MEETING of this section was held on Dec. 6th, Dr. LLEWELYN POWELL, the President, being in the chair.

Dr. F. S. ROOD opened a discussion on the Present Position of Spinal Anæsthesia. He said that he had nearly always used a 5 per cent. solution of stovaine, the density of which was increased by the addition of 5 per cent. of dextrose. He preferred this to a solution of stovaine in saline. The difficulty of the conscious patient was overcome by combining general anæsthesia or a modification of twilight sleep with spinal anæsthesia. The question of shock was discussed, spinal anæsthesia having been given up in the military hospitals in France owing to the danger of administering it to patients who would be seriously affected by a fall in blood pressure. On the other hand, spinal anæsthesia protected patients from the onset of shock due to prolonged and severe surgical procedures. Difficulties due to a fall of blood pressure in his own cases had been much less frequent since the adoption of the recumbent position. Dr. Rood's paper will appear in full in a later issue of THE LANCET.

Mr. P. LOCKHART-MUMMERY said that the object of anæsthesia was to protect the patient from loss of vital energy, which occurred in two ways: (1) by afferent impulses reaching the brain from the site of operation; and (2) by fear. Inhalation anæsthesia protected the patient against fear, but not against impulses reaching the brain; spinal anæsthesia protected against pain but not against fear, and fear affected the patient as much as pain in producing a lowered blood pressure. It was therefore advisable to use both forms. The best results he had seen yet had been from a combination of twilight sleep and spinal anæsthesia, but it was difficult to estimate the amount of scopolamine-morphine needed. The greatest advantage of spinal anæsthesia was that it did not produce vomiting. It was necessary to keep up the vital energy by feeding, and with spinal anæsthesia the patient could be fed until the time of the operation, and food could be given immediately afterwards. This made a very marked difference. During the last five years he had reduced his mortality from excision of rectum from 30 to 40 per cent. to 5 per cent. With regard to the question of shock, it should be realised that under spinal anæsthesia the patient was under the influence of gravity (the case being comparable to that of the hutch rabbit) and so must be kept head downwards. The careful moving of the patient afterwards was of extreme importance.

Mr. P. P. COLE said that with regard to the prevention of shock, the posture and the maintenance of the same position after operation were both very important. Such operations as that for a large umbilical hernia in a very stout woman should not be done without spinal anæsthesia, owing to the strain on the stitches when vomiting occurred. If vomiting were eliminated the success of the operation was assured. Spinal anæsthesia was also invaluable in prostatectomy and for all urethral work; with it he had never found an impassable stricture. It was also very useful in emergency operations in acute abdominal conditions where the surgeon was single-handed.

Mr. ROBERT DONNELLAN said that he had administered spinal anæsthesia for some years in thousands of cases. He preferred the saline form, because the operation could be begun at once and because pallor, sweating, shock, and collapse were less than with the glucose solution. Temperament played a large part; there was far more shock, sweating, &c., in the case of nervous patients. He asked if stovaine was a vaso-dilator. He had watched the pulse and had found the radial pulse large, soft, and flabby before shock came on. He had had a certain number of cases of retention of urine due to atony of the bladder, in which catheterisation was needed for some days.

Mr. H. M. PAGE said that he had begun by using the heavy solution and had gone on to the light, and did not wish to change. With the patient in the Trendelenburg position he had seen no shock, vaso-dilation, collapse, &c. Paralysis of eye muscles and headache also occurred after spinal puncture for fluid.

Dr. F. E. SHIPWAY thought that the fall of blood pressure was the chief question. It did not depend upon the lightness or heaviness of the solution used so much as on the paralysis of a large portion of musculature. He asked if the headache was a nervous phenomenon and due to the patient being apprehensive.

Dr. J. BLOMFIELD thought that Crile had underrated the power of general anæsthesia in preventing shock. It was difficult to produce shock in anæsthetised animals. Spinal anæsthesia was of great value in selected cases; he found it of most value combined with general anæsthesia.

Dr. ROOD, in reply, said that a fall of blood pressure superimposed on shock was dangerous. If the patient were in such a condition it was unsafe to give an anæsthetic which cut out the splanchnics. He had never seen a case of continuous retention of urine.

DEVON AND CORNWALL SANATORIUM FOR CONSUMPTIVES, DIDWORTHY.—The fifteenth annual report shows that during the year 148 patients were admitted in the first stage of tuberculosis, 155 in the second stage, and 20 in the last stage. Of the last-named cases half were discharged improved. The average stay of each patient was 90 days. The average cost per case amounted to just over 35s. weekly. The income was £5883, and an unfavourable balance of £191 remained.

Reviews and Notices of Books.

I. *A Short Practice of Midwifery.* By HENRY JELLETT, B.A., M.D., F.R.C.P. Irel. Seventh edition, revised. With 4 coloured plates and 236 illustrations. London: J. and A. Churchill. 1918. Pp. 545. 12*s.* 6*d.* net.

II. *A Short Practice of Midwifery for Nurses.* By HENRY JELLETT, B.A., M.D., F.R.C.P. Irel. Fifth edition, revised. With 6 plates and 169 illustrations in the text; also an Appendix and a Glossary of Medical Terms. London: J. and A. Churchill. 1918. Pp. 464. 8*s.* 6*d.*

I. THE present edition of this well-known text-book has been revised and seen through the press under the stress of war conditions in Flanders. In spite of this, the revision appears to have been carried out carefully and thoroughly, and it remains one of the best short text-books on the subject of midwifery. Naturally, it reflects the teaching of the Rotunda School, of which the author is so widely known an exponent. In the chapter on Eclampsia we notice that the rapid emptying of the uterus is not regarded with much favour. The question is a difficult one, but in view of the increasing number of advocates of the rapid termination of the pregnancy by the performance of Cæsarean section it is interesting to note the recommendation that if the patient's condition is becoming worse in spite of the medicinal treatment advised the uterus should be emptied after the use of Champetier de Ribes's bag or Frommer's dilator. Surely a more rapid and more surgical method in such a case is the performance of an abdominal Cæsarean section. The uterus can be emptied with greater safety by this method than by any vaginal operation. But apparently the author rejects Cæsarean section altogether, and would use in preference a Frommer's dilator, an instrument the employment of which most obstetricians have abandoned. It must be admitted, however, that the routine medicinal treatment as practised by the author and others, such as Stroganoff, has given very good results. A work which has reached its seventh edition requires no recommendation on our part; we endorse the favour with which it has been received by students and teachers.

II. The present edition has been carefully revised and brought into conformity with the existing practice of the Rotunda Hospital. A number of new illustrations have been added and others have been redrawn. As Dr. Jellett points out in his preface, the first duty of a nurse when the labour she is attending is not a normal one is to send for medical assistance, and her second duty is to do the utmost for her patient that she can until assistance arrives. She cannot perform the second of these duties, nor can she give intelligent aid to the medical man, if her knowledge is limited to the bare essentials which will enable her to conduct a case of normal labour. For the purpose of acquiring a theoretical knowledge of the other details of the management of a pregnant, parturient, and puerperal woman, a nurse cannot do better than consult this book by Dr. Jellett. In it she will find clearly and concisely described all the facts she should know, and we can confidently recommend it to all nurses studying midwifery.

Gynecology. By WILLIAM P. GRAVES, A.B., M.D., F.A.C.S., Professor of Gynæcology at Harvard Medical School, &c. With 368 half-tone and pen drawings by the Author, and 123 microscopic drawings and 100 illustrations in colour. Second edition, thoroughly revised. London and Philadelphia: W. B. Saunders Company. 1918. Pp. 883. $7.75.

IN the second edition of this book the section on the relationship of gynæcology to the internal secretions has been rewritten almost entirely and considerably amplified. This subject is one of the greatest importance to the gynæcologist, and how thoroughly it is treated by the author is shown by the fact that he devotes some 130 pages to it. A new section also has been added dealing with the relation of gynæcology to the sex-impulse, largely based upon the theories of Freud regarding infant sexuality. Other interesting additions are to be found in the sections dealing with ovarian organotherapy, ovarian transplantation, the radium treatment of cancer, and the use of radium in non-malignant gynæcological diseases. A special description is given of the very thorough operation for cancer of the vulva in two stages recommended by Taussig. Indeed, the portion of the book dealing with operative gynæcology is particularly interesting, as a number of operations are described which are not to be found in the ordinary text-books—for example, the author's method of performing anterior colpoplasty, Clark's perineoplasty, and Studdiford's modification of the same operation. Another useful procedure described is Bartlett's method of transplanting a portion of the fascia lata from the thigh in the treatment of ventral hernia. The whole work is most interesting and beautifully illustrated, upon which we can heartily congratulate the author, and it should be read by all teachers of gynæcology.

Simplified Method of Tracing Rays through Any Optical System. By LUDWIK SILBERSTEIN, Ph.D. London: Longmans, Green, and Co. Pp. 37. 5*s.*

THERE is something very fascinating about the apparent (but deceptive) simplicity of quaternions and vector analysis, but it is well to remember that such a good mathematician as Lord Kelvin confessed that for years he was unable to understand Heaviside's vector analysis. Dr. Silberstein, however, tells us in his preface that only the rudiments of vector algebra are involved in this little book, and that "a reader who is entirely ignorant of the subject could in a few hours acquire this amount of knowledge from one of the existing treatises on it." We think the author has underestimated the elusiveness of the method. For instance, on p. 17 a simple vector formula is said to show

"at a glance an interesting and perfectly general property of the prism. ..... Thus the final emergent ray makes with the edge (!) the same angle θ as the original incident ray, whatever its orientation. In other words, the only effect of the prism is to *turn the ray rigidly round the prism edge* as axis." (The italics are the author's.)

This statement is not a mere slip, for it is repeated on p. 27. It is, however, well known that the deviation of a ray due to the interposition of a prism is the angle between the incident and emergent ray, so that the axis, about which the ray is turned, passes perpendicularly through the intersection of these rays, and not through the edge of the prism. The book cannot therefore be recommended in its present form, and the 18 blank pages at the end might well be utilised in the explanation of the fundamental principles of vector analysis required in tracing rays by this method.

Reminiscences of a Student's Life at Edinburgh in the Seventies. By ALISMA. Edinburgh: Oliver and Boyd. 1918. Pp. 115. 4*s.*

THIS is a pleasant, modestly written little book of recollections of various events and people, and we may at once say that the people are far more important than the incidents which are mentioned in connexion with them. "Alisma" plunges at once into his subject with a reminiscence of Professor John Hutton Balfour, Professor of Botany (1845–79), who had told "Alisma" a botanical riddle the answer to which is the calyx of the wild rose, and it ran thus:—

Quinque sumus fratres, unus barbatus et alter,
Imberbesque duo, sum semiberbis ego.

(Two of the sepals of the calyx are bearded, two are not, and one is bearded on one side only.) This riddle in one form or another is of great antiquity, and John of Gaddesden, our first English Court physician, used it to describe the sections of his Rosa Anglica in this form:—

Tres sunt barbati, sine barba sunt duo nati,

signifying that of the five books into which his treatise was divided three were long and two were short.

Among other names of famous men mentioned by "Alisma" are Blackie, Crum Brown, Chiene, Christison, Turner, Huxley, and Lister. The last chapter recounts how the author returned after a lapse of 15 years to receive his Doctor's degree, and how he experienced that mournful feeling of loneliness which all of us who have been educated at a public school or university have felt on returning to the scenes of our youth. But the book will recall pleasant memories to all Edinburgh men of the period dealt with, and will serve for some half-hour to make them renew their youth as the eagle when [illegible] read it.

THE LANCET.

LONDON: SATURDAY, DECEMBER 14, 1918.

Medicine and Aviation.

THE Report of the Civil Aerial Transport Committee, issued last week by the Air Board, makes it certain that the developments of aviation during four years of war will find expression in the life of the world during the peace upon which we are now entering, and within which we aspire to abide for the future. The report indicates that certain types of flying machines will be promptly available for use upon the air routes of the globe, not only for mail and parcel traffic, but also for business, travel and even pleasure touring. With respect to the organisation of this tremendous revolution in transit and transport much, of course, remains for discussion. Of the character of the machines, it is obvious that they will have to be made to suit the circumstances of their employment, and elaborate rules will have to be laid down for the maintenance of certain streams of traffic. Similarly, the establishment of adequate aerodromes will be required, as well as landing-stages and garages, so that convenient starting- and stopping-places may be at public disposal. Systematic meteorological observations will have to be arranged, and as some of the activities postulated will not only entail flying by night, but to some extent flying at regular intervals in accordance with a time-table, weather forecasts will be needed, as well as knowledge of air currents at high altitudes. All this information must be forthcoming and available for ready distribution. It is clear that before a regular commercial air service can be established a vast amount of preparation remains to be undertaken.

But that regular aircraft services for various purposes will come into being no one can doubt who has followed in imagination the intensive experience obtained by the flying services in the course of the war—experience that will be largely wasted unless it is to form the foundation of the new developments. This experience has been of a terrific character, associated in many cases with violent death and permanent injuries, although the highest medical talent has been freely placed at its disposal. Without this medical service, which grew up almost within a night at the call of urgent need, flying would still be in large measure the approach to suicide which it was a decade ago. Obviously, the pleas which have been put forward for a first-rate medical service attached to the Royal Air Force during the war hold good also for the aviation service which peace brings in. The human bird, whether vulture or carrier-pigeon, is exposed to many and peculiar strains requiring close and special medical supervision if accident is to be avoided. The flying man is an artificial combination in which man and machine become to all intents and purposes one. Histologically such a symbiosis has generally taken æons to evolve. The last few years, and especially the last year of all, have seen its meteoric development in the airman; but its maintenance will for that very reason require the more systematic care. The principles on which personnel is chosen will require working out. The physiology and psychology of candidates for service must be closely scrutinised, as the responsibility in life and limb of the recruiting officer will be a very heavy one. Recruiting officers must form part of a highly equipped and properly trained service. Of all factors probably the most important in the art of flying is the coördination and prompt action of reflexes necessary for the successful management of mechanical accessories which have become part of the human person. It has been stated, and we have never seen it contradicted, that in practically no other accomplishment has the man to keep so many groups of antagonistic muscles in a state of static wakefulness, or to perform such a variety of coördinated leg and arm movements. The statement was made with reference to the management of fighting machines, where alone experience can be quoted. But while the more stable commercial machines will not make such demands, the need will still remain that the period of training for flying should be adequately long; and it also means that the candidate, when found physically fit to fly, should be able to call during his training for the best medical advice, and to feel that he is receiving responsible care, which does not mean grandmotherly supervision.

How the selection of aviation candidates is to be accomplished is the subject of an exhaustive article by Dr. G. A. SUTHERLAND in our columns this week. Medical examination of would-be-flyers is the first link in a chain which should support every flying service at every stage. Dr. SUTHERLAND, writing as a late member of the Special Medical Board of what was the Royal Flying Corps, begins with detailing the essential qualifications for air service, and goes on to indicate the special conditions of the cardio-vascular and nervous systems which make the candidate a likely or an unlikely flyer. This examination involves points more difficult than the essential integrity of the sense organs, which is comparatively easy to determine. Only during a preliminary period of probation will some of these points become clear. Ground training of candidates will include athletic sports, not only to keep them fit but to afford medical indications both on the physical and temperamental sides. Much has been said that is wise, and much that is less than wise, concerning the temperament of the aviator, and a large proportion of these reflections have been made with the fighting man alone in mind. Aviation, when it becomes a branch of the Civil Service or a part of our domestic machinery, will remain for the present a dangerous occupation, or we should not be claiming that those who pursue the occupation should have at their beck and call a highly qualified medical service. But with the disappearance of war there goes a class of risk which called for an ultra-courage and activity. For those heroic

souls, whose absolute fearlessness, love of adventure, determination to overcome difficulties, and devoted patriotic obedience played so large a part in the war, a white-hot enthusiasm was necessary which will hardly be at the disposal of commercial life. And with that fact vanishes the force of much of the lurid writing about the temperament of the flying officer, but in no way whatever is proper medical supervision of commercial flying rendered unnecessary. It is urgently necessary.

Beer, Germinated Beans, and Scurvy.

THE processes of seed germination and the complex and interesting changes involved therein have long attracted the attention of chemists and biologists. The subject received the most earnest and fruitful study when science came to the aid of the brewing industry, and it is worthy of observation that both chemical and biological science gained greatly by the researches connected with the brewing of beer. The maltster did but imitate the natural processes of germination by soaking the grain in water under favourable conditions until it sprouted—a period of growth which meant the beginning of important changes in the constituents. It meant the development of the enzyme which transformed insoluble starch into soluble sugars, and these being capable of fermentation became further simplified and were succeeded by alcohol showing the constitution of water, in which one hydrogen atom is replaced by the ethyl group. That seems simple chemistry enough, but the changes are more complex than thus described, for besides dextrins and sugars there are other very important products elaborated which, though present in minute amount, are now found to exercise a remarkable influence on the human metabolism. In an interesting historical sketch which we publish this week, by Mrs. ALICE HENDERSON SMITH, on "Beer and Scurvy," reference is made to the value of fresh germinated barley as a material possessing marked antiscorbutic potency, which is preserved in the beer produced from the malted product so long as it is not dried at too high a temperature. In an account in THE LANCET of Oct. 19th of an outbreak of scurvy in the South African Labour Corps Dr. HAMILTON W. DYKE observed the useful place taken by kaffir beer in the diet of these natives, which would appear to confirm and justify the belief in the value of beer as an antiscorbutic used in the Navy 120 years ago. Under, however, modern methods of malting and brewing the antiscorbutic element appears to be largely, if not completely, eliminated. Recent experiments, again, made by A. HARDEN and S. S. ZILVA with beer made from kilned malt led to the conclusion that the malt liquor so made was deficient in antiscorbutic properties, a conclusion which explains the history of its failure as a defence against scurvy in certain of the Arctic expeditions. Beer made by modern methods may therefore be ruled out as of any value as an antiscorbutic, but the fact that the process of germination develops an antiscorbutic factor must not be lost sight of.

In describing the distribution among foodstuffs of the vitamines needed for the prevention of beriberi and scurvy, Dr. HARRIETTE CHICK and Miss E. MARGARET HUME[1] have demonstrated by animal experiments that germinated pulses are richly endowed with antiscorbutic vitamine, and they made the practical suggestion that in order to prevent scurvy, if a supply of fresh fruit is not procurable, germinated pulses should be added to the diet. In our columns this week we publish a very interesting note "On the Value of Germinated Beans in the Treatment of Scurvy and Some Points on Prophylaxis," by Dr. H. W. WILTSHIRE, who had under his observation in 1917 many Serbian soldiers affected with scurvy, and when the disease became prevalent again this year an attempt was made to test the value of germinated pulses in treatment. The clinical results he reports confirm the experimental results of Dr. CHICK and Miss HUME, and "permit the definite conclusion that dry beans develop, upon germination, an amount of antiscorbutic vitamine at least equal to, if not greater than, that contained in fresh lemon juice." The results are remarkable, for they show that the use of germinated pulses is capable of practical application for the effective prevention of scurvy, and in the opinion of Dr. WILTSHIRE this would be the easiest and cheapest method by which to prevent the occurrence of scurvy in an army in the field.

All this should give fresh stimulus to probe further into the exact nature not only of these antiscorbutic elements, but of the antineuritic elements also. In neither case has a specific substance been isolated, and consequently no definite chemical constitution can be ascribed to them. It would appear that all attempts to isolate an exact substance by well-known methods of separation are frustrated by an instability of character. These accessory food substances, for instance, will not survive prolonged heating and alkalies are fatal to their activities, which would seem to point to their being of a basic nature, the alkali setting free possibly a nitrogen group. We know that the antineuritic element can be differentiated from the antiscorbutic element by adsorbents. Fuller's earth, for example, adsorbs, as HARDEN and ZILVA have shown,[2] almost quantitatively the antineuritic factor out of autolysed yeast, but does not reduce the antiscorbutic potency of orange juice, so that in a fluid containing autolysed yeast and orange juice the antineuritic factor is removed, while the antiscorbutic activity remains unimpaired. The same authors[3] have shown, again, that by eliminating the free citric and other organic acids in lemon juice an antiscorbutically active residue is obtained, and therefore these organic acids are not concerned in the prevention of scurvy.

[1] Harriette Chick and E. Margaret Hume: The Distribution Among Foodstuffs (especially Those Suitable for the Rationing of Armies) of the Substances Required for the Prevention of (a) Beri-beri, and (b) Scurvy, Journal of the R.A.M.C., xxix., No. 2, August 1917, p. 121.
[2] THE LANCET, July 13th, 1918, p. 52.
[3] Biochemical Journal, October, 1918.

It is to be hoped that the chemistry of these accessory factors will soon be cleared up and a method found for their isolation in the pure state. Biologists have done well in developing this new scientific aspect of dietetics, and so far chemists have not kept pace with them. We may appropriately, in connexion with the whole subject, congratulate Professor FREDERICK GOWLAND HOPKINS, University Reader in Chemical Physiology and Prælector in Bio-chemistry in Cambridge University, on having been awarded at the last annual meeting of the Royal Society, held on St. Andrew's Day (Nov. 30th), the Royal Medal of the society. As stated on the occasion of the presentation of the medal, Professor HOPKINS was among the very earliest, if not actually the earliest, to recognise and announce that minute quantities of certain bodies, the nutritive value of which had hitherto been unsuspected, exert an enormous influence upon growth and upon normal adult nutrition. He showed that without these accessory factors a diet otherwise full and seemingly complete is incapable of allowing growth and even of maintaining body-weight or life. Subsequent events have abundantly proved what a valuable observation in dietetic research was thus made.

Demobilisation and Venereal Diseases.

THE Local Government Board is alive to the very pressing danger of the mobilisation of venereal diseases on demobilisation of the Armies to which we made extended reference last week. The Board has issued a circular (V.D.19) to county and borough councils, asking them to secure at once a considerable extension of facilities for the free treatment of venereal diseases. In the first instance arrangements are suggested for more frequent clinics, including evening sessions at existing treatment centres, and in the second for the provision of additional centres. The Board suggests that in many cases it will not be practicable to provide sufficient centres by arrangement with the voluntary hospitals, and that it will therefore be necessary for the borough councils to make arrangements on their own premises, possibly utilising a tuberculosis dispensary or isolation hospital. For the treatment of gonorrhœa, in the intervals between the clinics treatment by a trained nurse or attendant (subject to medical supervision) is suggested, the treatment to be given either at the hospital where the treatment centres are or at new auxiliary centres. The latter should also serve the requirements, between the dates of attendance of the doctors at the regular clinics, of persons who are apprehensive that they may have contracted disease, although no medical diagnosis has yet been made. Borough councils of the larger areas are urged to consider at once the desirability of appointing whole-time venereal disease officers. Negotiations are proceeding with the naval and military authorities for the early release of doctors specially experienced in the treatment of venereal diseases, of whom a list will shortly be available.

Annotations.

"Ne quid nimis."

A NATIONAL TRIBUTE TO VOLUNTARY AMBULANCE WORKERS.

A LETTER from Lord Ranfurly in another column calls attention to the admirable work, extending over 40 years, which has been done by the Ambulance Department of the St. John Ambulance Association. And in our correspondence columns last week Sir Rickman Godlee and Sir James Cantlie, respectively President and Principal of the College of Ambulance, Vere-street, W., entered a plea for funds in order that the College may have an assured income, and be enabled to carry out in peace time the useful—the immeasurably useful—work which it has done during the war. Everyone should recognise the important part which first-aid teaching has played in the saving of life during the war, while the Home Office regulations with regard to emergency treatment in factories is a proof of the value of prompt surgical aid in the civil direction. First-aid is, indeed, an essential adjunct to medicine and surgery; immediate attention after injury, wherever it may take place and by whatever means, often saving lives, and always assisting treatment. It should be realised that men, women, and children of these islands also leave the homeland to reside under unusual climates and in thinly populated districts, as the need of the workers dictates, and these localities are surrounded by many dangers to health which are new to them, and which present themselves in circumstances where the threatened persons are bound to depend on their own ingenuity. A part of the work of the College of Ambulance is to guard against these dangers. At any time the healthy individual life is an asset to the nation, but at the present moment such a life has an artificial value when war has left its hideous mark on the population. The College of Ambulance was founded in September, 1914, when Sir James Boyton gave the magnificent buildings, 3, Vere-street, London, as a home for the College free of rent for a year, the expenses of the work being paid in part by the fees of the pupils, and Sir James Cantlie giving his services as teacher free. In September of the present year the incorporation of the College took place, and now, if the institution is to form a sufficiently noble memorial to the thousands of voluntary workers who have given their services to the country in time of need, and adequately play its part in the reconstruction work that is before us, it is necessary that substantial financial aid should be forthcoming. The very nature of the work prevents it from being self-supporting, for large teaching fees cannot be asked from those who freely give their services to the country without pay. The sum required to establish the association on a permanent basis as a national memorial is £100,000, and Lord Mount Stephen has started the list of subscriptions with £500. We hope the appeal will receive the whole-hearted support of both the public and the medical profession. Subscriptions should be sent to the Honorary Treasurer, 3, Vere-street, London, W. 1.

AN ANOMALOUS DISEASE.

THERE was a curious epidemic at Taranto in May and June of this year, attacking the civil population and the crews of the men-of-war. Ships might

have three or four hundred cases on board in a very few days. Luckily the cases only lasted two days usually. The very young and the very old were not attacked. The disease was clinically differentiated from dengue, influenza, and pappataci fever, and a *Micrococcus tetragenus* was found in the blood and pleural exudate; a streptococcus was sometimes present. The disease was characterised by pharyngitis, headache, pain in the back, pyrexia (104° even), and in severe cases pneumonia, pleurisy, albuminuria, enlargement of spleen. Endocarditis is mentioned in the post-mortem report of ten fatal cases. Gargling the throat is mentioned as a prophylactic, and in treatment aspirin is forbidden, as weakening of the heart is specially feared. Relapses did not occur, so some immunity is probably set up. We quote from the report of Lieutenant-Colonel Saccone in the *Annali de Medicina Navale*.

WAR NEPHRITIS OR TRENCH NEPHRITIS.

AMONG the many controversial questions raised by the conditions of medicine and surgery which seem to be directly dependent upon war the problem of war nephritis or trench nephritis occupies a prominent place. There seems to be little doubt that its incidence is determined entirely by war conditions. It affects almost exclusively troops in the front line, civilians having in great proportion escaped. Few cases occur amongst officers or in units that are well housed. Numerous theories have been evolved, most of them speculative in character and based upon little evidence, though there seems to be an increasing consensus of opinion in favour of an infective agent in the causation. We published in a recent issue of THE LANCET an admirable summary of the clinical features of this disease by Professor H. B. Day,[1] Professor of Clinical Medicine, Egyptian School of Medicine, based upon a careful personal study of 50 cases in the early stages and a critical examination of the records of other observers. Professor Day excludes the cases of recurrent nephritis and of infective nephritis with more or less obvious primary focal disease, and bases his observations on what may be regarded as war nephritis or trench nephritis proper. This he divides into two main groups—the common form characterised by breathlessness, œdema, and the urinary signs of acute nephritis, and a smaller group distinguished by hæmaturia and involvement of the lower urinary tract, which he follows Dr. R. G. Abercrombie in calling "lower tract cases."[2] Professor Day finds, in agreement with Dr. Abercrombie, that the onset of war nephritis is almost invariably associated with fever which may be of very short duration, so that the general course of the disease is in the main afebrile. He points out that pains in the limbs and back occur, often severe enough to keep the patient awake, and also observes that the spleen was enlarged in all of his cases, and that it became actually palpable in 50 per cent. of them. Professor Day was early impressed with the periodicity of some of the manifestations of the disease. He found that the daily output of urine increased at regular intervals or that it might show periodical falls with a temporary increase of the albuminuria or a visible return of hæmaturia. Such slight recurrences or relapses were often associated with a distinct febrile reaction lasting three days, with a change in the pulse-rate and a fall of blood pressure. Professor Day has observed in cases of trench fever a periodic variation in the enlargement of the spleen which occurs in that disease. He found that the spleen showed alternate advances and recessions in size at regular intervals of five or six days. In war nephritis he noted an exactly similar condition, the spleen varying in size with a periodic variation of identical character. The illustrative details of some of his cases were accompanied in the contribution to our columns with charts showing the variations in temperature, quantity of urine, and splenic enlargement, and his observations were summarised by claiming that the course of war nephritis is marked by more or less evident changes at regular intervals of five or six days—a feature which it shares with trench fever—and he asks whether war nephritis is a complication of trench fever. He admits that the actual proof or disproof of this hypothesis can only be settled by experimental and laboratory work. His reflections are of such interest that they should attract the attention of other observers to this question.

THE MEDICAL PARLIAMENTARY COMMITTEE.

MEETINGS of the Executive Committee of the Medical Parliamentary Committee have taken place since our last issue, at which the work ahead was discussed. Coming into existence at so short a period before the General Election the Committee could not expect to play any prominent part in the election; but its offer to supply medical speakers to medical candidates has been welcomed in several directions. The fact that the Committee takes no cognisance of party distinctions will thus be made apparent on several platforms, and in this way the public will see that the Committee is standing for the principle that the medical profession should receive a full share of responsibility in the inception and administration of national health legislation, because the foundation of national progress is national health.

A NEW SIGN OF FOREIGN BODY IN THE TRACHEA OR BRONCHI.

IN the *American Journal of the Medical Sciences* for November Professor Chevalier Jackson has called attention to a new sign of foreign body in the trachea or bronchi which he terms the "asthmatoid wheeze." Further help in the diagnosis of such a body is desirable, for the usual methods—auscultation, percussion, and the X rays—though valuable when positive, do not allow the conclusion to be drawn that a foreign body is absent when they are negative. The new sign is called the "asthmatoid wheeze" because it is similar to the wheezing heard when the ear is placed close to the mouth of an asthmatic. The chief difference is that with the latter râles are more or less associated. In the case of the foreign body the sound is drier when typical, though it may be associated with the bubbling sounds arising from secretion. In a typical case the wheeze is much more marked after coughing out of all secretion than before. This is probably because secretion more or less occludes the spaces by which air escapes between the wall of the bronchus and the irregularly shaped foreign body. When cleared out more air passes and the wheezing is louder. Numerous cases of foreign body in the air passages are reported in which

sounds have been heard with the stethoscope or ear applied to the chest wall or over the cervical trachea or larynx, but the sounds emitted from the open mouth do not appear to have been studied. The nearest approach is the "croupy cough" mentioned as indicative of a foreign body in the larynx, but it is not in laryngeal cases that the "asthmatoid wheeze" is heard. If there is croupy cough the larynx must be looked at. But the indications for bronchoscopy are not so clear. The "asthmatoid wheeze" is elicited by placing the ear in front of the patient's open mouth while breathing deeply and regularly, and is heard during expiration. If wheezing is not noticed the patient is asked to carry respiration to the extreme limit, as though endeavouring to expel all residual air. In a number of cases the wheezing has been apparent only at the termination of this prolonged forced expiration. In others it was so loud as to be noticed all over the room. Care is necessary to distinguish between wheezing due to secretion and wheezing due to a foreign body. This cannot always be done with certainty. Moreover, secretion is usually present in the neighbourhood of a foreign body. As a rule the sounds of secretion disappear after cough and expectoration, while the wheeze of a foreign body remains after the most violent coughing unless the body has been shifted. Of 62 cases, in which the presence of a foreign body was proved, Professor Jackson found the wheeze in 41. It would not, of course, be produced by a smooth foreign body which corks a bronchus tightly.

THE MEDICAL DIRECTORY FOR 1919.

WE have received the Medical Directory for 1919 a few weeks earlier than last year, and take it as the harbinger of a return to more normal conditions in the publishing world. The number of names in the Directory is now 43,100, being an increase of 69 over last year, which itself showed an increase of 152 over 1917. The London total shows an increase of 30, while 119 fewer names are recorded in the provinces, the deficit being made up in Wales, Scotland, and Ireland. But these numbers have special sources of fallacy at the present time. It would have been easy to state the numbers of men and women respectively in the total list or in the respective sub-lists, and we are sorry that this has not been done. The number of women is commonly stated at between 1500 and 2000, which is only a rough approximation to the truth. The useful section summarising the principal laws affecting the medical profession has been brought up to date, and enumerates the drugs prohibited from sale to members of the Forces, with the recent additions of acetanilid and phenacetin. The Honours List in the Directory is no longer complete; the Order of the British Empire has been omitted altogether, as well as the Companions of the various Orders and the holders of the Victoria Cross, the Military Cross, and the Distinguished Service Cross. If the V.C. is not to count as a distinction worthy of record, it is a little difficult to see what is, but of course many holders of this distinction have not survived its bestowal. The high standard of accuracy we have been led to expect is maintained in this new edition.

THE House of the Royal Society of Medicine will be closed from Monday, Dec. 23rd, to Saturday, Dec. 28th, inclusive, but the Library will be opened to military medical officers except on Christmas Day and Boxing Day.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE time is approaching in the opinion of the Committee of Management of this Fund when a decision will have to be made as to the future of the Fund. The money in hand is nearly exhausted, and the war is over, but the needs remain, and what part, if any, the Fund can still play in meeting these needs must soon be determined.

Sir RICKMAN GODLEE, the Chairman of the Committee, has received the following letter from Dr. V. Pechère, the President of the Comité National de Secours et d'Alimentation, representing the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés; this is the representative Belgian Committee, sitting in Brussels, to which the mensualities of the Belgian Doctors' and Pharmacists' Relief Fund have been transmitted for distribution, while the *comptes rendus* of this Belgian body have been summarised frequently in our columns and those of our contemporaries, to show alike the receipt of our contributions and the manner of their allocation. Dr. Pechère writes:—

Bruxelles, Rue des Drapiers, 25.

MON CHER COLLÈGUE,—La guerre est virtuellement terminée. Le droit et la justice triomphent du mensonge et de la force brutale.

Les derniers soldats allemands quittent Bruxelles. Demain il n'y en aura plus un seul dans nos murs. On me dit que les communications postales sont rétablies entre la Belgique et l'Angleterre; et je trouve un ami qui part demain pour Ostende. Je saisis avec empressement cette occasion pour lui confier ces lignes qui, cette fois,—j'en ai l'espoir,—vous parviendront.

Elles iront vous dire en mon nom et au nom de mes collègues l'hommage ému de notre reconnaissance. Le moment n'est pas aux longs discours. Un mot résumera tous les sentiments dont nos cœurs débordent et dont, plus tard, nos lèvres essayeront de vous traduire l'expression. Ce mot, c'est: Merci!

La nation belge sait et n'oubliera jamais ce qu'elle doit à l'Angleterre et à ses alliés.

Les médecins et pharmaciens belges savent et n'oublieront jamais ce qu'ils doivent à leurs confrères anglais et à tous ceux qui ont contribué par leur générosité à soulager leurs misères.

Grâce à vous, grâce à eux nous avons pu sauvegarder la dignité morale de nos confrères nationaux, et les tirer d'une détresse matérielle que nos moyens professionnels eussent été impuissants à combattre.

Votre témoignage constant de solidarité corporative a été pour le corps médico-pharmaceutique belge un précieux et perpétuel réconfort.

Soyez-en remerciés, tous, du plus profond de notre cœur. Nous vous adresserons sous peu un rapport complet sur l'activité de notre œuvre commune.

Croyez, mon cher collègue, à mes sentiments les meilleurs.

Vivent les Alliés! Rule Britannia! Vive la Belgique!

Votre dévoué,
DR. V. PECHÈRE.

Sir Rickman Godlee, Président du Belgian Doctors' and Pharmacists' Fund.

SUBSCRIPTIONS TO THE SECOND APPEAL.

The following subscriptions have been received up to Monday last, Dec. 9th:—

	£	s.	d.
Dr. H. O. Williams ...	2	2	0
Mr. S. Osborn	1	1	0
Dr. C. C. S. Watson ...	5	0	0
Woolwich and Lewisham Divn. B.M.A. (per Dr. C. J. Fuller, hon. sec.)	7	0	0
Sir Alfred Pearce Gould (monthly)	5	0	0
Ross and Cromarty Divn. B.M.A. (per Dr. E. Mackenzie, hon. sec.)	8	17	6
Mr. E. Boulanger	7	15	8
Royal Faculty of Physicians and Surgeons of Glasgow	26	5	0

Monthly Subscriptions.

The following monthly subscriptions have been received for November:—

	£	s.	d.
Dr. Vincent Tighe... ...	0	10	0
Dr. G. Grey Turner ...	1	1	0
Dr. W. E. Good	0	10	0
Dr. W. Luffman	0	10	0
Dr. A. E. Naish	0	10	0
Dr. J. O. Musson	0	10	0
Dr. T. W. Goodbody ...	1	0	0
Sir T. Barlow	0	10	0
Surg. P. G. S. Davis, R.N....	0	10	0
Dr. A. B. Stevens	1	0	0
Major E. R. Fothergill...	0	10	0
Dr. W. S. Hart	1	0	0
Dr. A. Graham	1	1	0
Dr. Hyla Greeves	0	10	0
Dr. H. Caiger	0	10	6
Dr. K. J. Dougall	0	10	0
Dr. A. W. Forrest	1	0	0
Capt. H. L. P. Hulbert, R.A.M.C.	1	0	0
Dr. E. C. Morland... ...	0	10	6
Dr. H. Whitehouse ...	0	10	0
Dr. A. Hawkyard	0	10	0
Dr. W. Stewart	0	10	0

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE King has sent a donation of £5 to the Queen's Hospital for Children, Hackney-road, E., for the Christmas Fund.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

—o—

SATURDAY, NOV. 30TH.

The Case of Frederick Charles Beaumont, L.D.S. R.C.S.

THIS case having been referred to the Dental Committee to ascertain the facts, the committee now reported that they had received shorthand notes of divorce proceedings, in which a decree nisi and absolute had been obtained, with Mr. Beaumont as co-respondent, the respondent having at one time been his patient. Mr. Beaumont also, they reported, gave evidence before them.

The Council deliberated *in camera* on the case, and the PRESIDENT then delivered its judgment, which was that Frederick Charles Beaumont had been adjudged guilty of conduct disgraceful in a professional respect, and that the Registrar was instructed to erase from the Register his name.

The Apothecaries' Hall of Ireland.

Sir JOHN MOORE presented the report by the Examination Committee on various matters relating to the Apothecaries' Hall of Ireland. The report ran as follows :—

On May 31st, 1918, the Council received and entered in its minutes a report by the Examination Committee, and adopted the following recommendations contained therein :—

"1. That the report of Dr. William Boxwell and Dr. Robert Rowlette on the examinations held from December, 1916, to November, 1917, be forwarded to the Apothecaries' Hall of Ireland for their information, with the request that they will favour the General Medical Council with any remarks they may desire to make thereon, in time for the meeting of the Council in November, 1918

"2. That the Apothecaries' Hall be requested to continue to furnish the Tables of Exemptions from, and Results of, Examinations as heretofore, giving particulars of marks, and when the candidate had been previously examined by the Hall, and had passed some portion of the examination, the date of such examination."

These resolutions were conveyed to the Apothecaries' Hall of Ireland on June 5th, 1918.

On Nov. 11th the Apothecaries' Hall forwarded the following remarks on the report of Dr. William Boxwell and Dr. Robert Rowlette :—

"Apothecaries' Hall of Ireland, Mary-street, Dublin,
Nov. 11th, 1918.

The reports of Drs. Boxwell and Rowlette on the examinations held by this body have been considered by the Court of the Hall.

The Court desires to protest in the strongest possible manner against the continued reports and inspections on this institution.

The Court appoints examiners of the highest professional qualifications. Five are professors and one a lecturer in a recognised university; two are members of the Council of the Royal College of Surgeons, Ireland, while seven are members of leading clinical hospitals in Dublin. The Court therefore thinks that its Board of Examiners compares most favourably with any examining body in the United Kingdom, and considers that the perseverance of the General Medical Council in causing constant inspections to be made on the Hall to be due only to prejudice, and to be most unjust."

A Table of Exemptions from, and the Results of, the Examinations of the Hall, held in June, 1918, was received on Nov. 23rd, and is appended to this report. It calls for no comments.

Appendix to Report by the Examination Committee, Apothecaries' Hall of Ireland, June, 1918.

No.	Preliminary Examination. When and where passed.	Primary.	Intermediate.		Pharmacy.	A Medicine.	B Surgery.	C Midwifery.	Result.
			Anatomy, Physiology.	Pathology. Medical Jurisprudence and Hygiene, Materia Medica.

On Oct. 28th, 1918, the Hall intimated that it would hold examinations, including the Final Examination, covering the period Nov. 11th to 25th, 1918, and this was communicated to Dr. Finny, who had been deputed to attend these examinations on behalf of the Council during the current year. Dr. Finny thereupon consulted the Council as to when he should present his report, and on the instructions of the President he was advised that it would be expedient to submit one annual report. This may therefore be expected to be ready for the consideration of the Council at the May session, 1919.

The following draft recommendations concluded the report :—

1. That the Apothecaries' Hall be requested to continue to furnish the Tables of Exemptions from, and Results of, Examinations as heretofore, giving particulars of marks, and when the candidate had been previously examined by the Hall, and had passed some portion of the examination, the date of such examination.

2. That the Irish Branch Council be authorised to appoint for the period of one year a deputy to attend and be present on behalf of the General Medical Council at the professional examinations held by the Apothecaries' Hall for the purpose set forth in Section 18 of the Medical Act, 1858; that the deputy so appointed present to the Council a report on the general character of such examinations; and that he be paid a salary of £50 for the year in question.

The report having been received,

Dr. MAGENNIS said that he thought that an injustice had been done in the report to the Apothecaries' Hall. For five years he had done what he could to render the examinations of that body what they should be. After a couple of years of effort he induced this Council to make certain recommendations, and every recommendation which had been made had been carried out by the Apothecaries' Hall. The examiners would compare favourably with those of any examining body in the Kingdom. The only real objections seemed to have been to clerical errors in the examination papers and to the fact that on occasion it was difficult to get some of the examiners there in time. He asked what were the reasons for the exceptional treatment meted out to the Apothecaries' Hall? The Council insisted on a deputy being appointed, but he knew the animus which actuated their deputies.

The PRESIDENT said that the reason for this method of dealing with the Apothecaries' Hall went back to the appeal made by that Hall to the Privy Council against the General Medical Council, in which it appeared that the Council had refused to appoint examiners in surgery in a certain case on the ground that the appointment of examiners in surgery in that case would not help the Council to determine whether the examinations in medicine and midwifery were conducted in a proper way. The Privy Council directed the General Medical Council to appoint examiners in surgery, pointing out that they had means of obtaining efficiency in the other examinations. Those means were the appointment of a deputy from the Council, and other persons had also been appointed to look after the other parts of the examination, not in the way of fault-finding, but in order to know what took place. The proceedings had been quite regular and carried out the terms of the Privy Council.

Sir ARTHUR CHANCE thought the Council ought to resent any imputations cast upon it.

Sir JOHN MOORE said the Council was bound to see that the whole conduct of the examinations was up to the standard considered necessary by them. At page 29 of the Interim Volume (1917) of the Transactions, Dr. Boxwell said: "On these and other grounds I think the examination in pathology, as conducted at the Apothecaries' Hall, is definitely below the standard required by any other licensing body I know of." Page 31 contained a summary of Dr. Boxwell's conclusions: "What strikes one most about the examinations, taken as a whole, is a certain inequality in the standard. The examination in pathology, for instance, is badly planned, although well carried out as far as it goes; whereas others are, through the peculiarities of examiners, sometimes rendered nugatory. I refer to the indulgence shown to outrageous blunders." If this report were adopted, it would be necessary to meet in London to appoint a deputy.

The report was adopted.

Report of the Education Committee on the Nature of the Recognition to be extended to the Schools Examinations recently established by the Board of Education.

The Report was presented by the Chairman of the Committee, Dr. J. Y. MACKAY. A general description of the purposes for which these examinations had been instituted by the Board of Education in England will be found in the Minutes of the Council, Vol. LIV., 1917. The Report thus defined the certificates issued by the Board of Education to the successful candidates according in each case to the educational level attained :—

(1) The certificate of success in the "Second" examination, which follows on a specialised course of study, bears the names of the subjects in which the candidate has passed, and is accepted *pro tanto* by the Universities in respect of the subjects they themselves recognise as satisfying their regulations for matriculation. Similarly it is accepted by the General Medical Council.

(2) That form of certificate of success in the "First" examination in which the candidate has obtained a "pass with credit" in certain of the subjects bears the names of the subjects passed with credit; and in respect of these subjects, should they be included in the University and Council Lists, it is accepted *pro tanto* by the Universities and by the General Medical Council. Candidates who have already obtained the School Certificate may, in subsequent examinations, enter for subjects in which they have not previously passed "with credit," and success in such subjects will be recorded on Supplementary Certificates.

(3) That form of certificate in the "First" examination issued to candidates who have not passed with credit in any of the subjects is termed an "ordinary pass." In it the names of the subjects actually passed are not detailed, but only the "groups" to which the subjects passed belong. As the "groups" referred to are of a very wide nature, and as the Council, like the Universities, has always required that certain subjects should be included, and has allowed only a limited selection in the case of others in its entrance examination, it is certain that it cannot under its present regulations, and could not, without a profound change in the methods hitherto followed, accept either the "ordinary pass certificate" ((3) above), or, in particular cases, the special certificates granted under the "pass with credit" or the "second examination" regulations ((2) and (1) above).

The Report set out the scope of the examination and the general view taken consistently by the Education Committee of the Council and recommended to the Council as follows :—

That the Council endorses the proposal contained in the Report—viz., that the certificate of the "First Schools' Examination" of the Education Board in England be accepted as affording sufficient evidence that the holder has fulfilled the educational conditions required of candidates for admission to its Register of Medical Students, provided that the subjects of English and Mathematics have been passed "with credit."

Dr. MACKAY, in presenting this report, said it was hoped in time to reach the higher standard which the Council had always had as its object. A very important step had recently been taken by the English Education Board in establishing "leaving certificates." In the absence of these latter, the schools had been preparing for a large number of external examinations, and the teaching had suffered greatly owing to the pressure exerted to meet the necessities of all those examinations. The result of having a general education examination would be to free the schools from this pressure. A similar arrangement had been operative in Scotland for a number of years, and he hoped to see such an arrangement in Ireland. The important matter in the future would be the mental training which the student had received, not his proficiency, as tested by examination, in any set subjects; and the Council had chosen the subjects best suited to that end. He proposed the adoption of the report.

Dr. NORMAN MOORE seconded.

The PRESIDENT congratulated the committee on the successful issue of their long negotiations with the English Education Board. The Council desired that a system of examinations should be established which would harmonise all the examinations throughout the country. The merit of the new scheme consisted in the fact that it was based on education, not on examination only, no inquiry being made as to the source of the information.

Dr. LANGLEY BROWNE asked whether there might not be some difficulty due to some of the schools not knowing how to work the scheme.

The PRESIDENT replied that many of the Universities would accept the certificate; the whole machinery became automatic.

The report was agreed to.

Report of the Pharmacopœia Committee.

This report, which was adopted, was as follows :—

The number of copies of the British Pharmacopœia, 1914, which were sold by the publishers between May 26th, 1918, and Nov. 23rd, 1918, was 1512. The number sold in the year ending Nov. 23rd, 1918, was therefore 2382. The total number sold since the date of publication is thus 31,736. Of the third issue of 5000 copies, about 3200 remain in stock.

The Committee are informed that the conditions governing the supply of glycerin, sugar, fats, and oils do not yet permit of the withdrawal of the notices respecting emergency "Alterations and Amendments" of the Pharmacopœia issued during the war.

The Ministry of Public Health.

The Council, sitting *in camera*, discussed the Bill to establish a Ministry of Health and a Board of Health to exercise in England and Wales and in Scotland respectively powers with respect to health and local government. (See THE LANCET, Nov. 16th, p. 685.)

On resuming after the sitting *in camera* the President announced that the Council had passed the following resolution :—

"The General Medical Council cordially supports the proposal to establish a Ministry of Health, and requests the Lord President to submit for its observation the draft of any future Bill on the subject. The Council hopes that any such measures may be applied in its general terms to all parts of the United Kingdom."

The report of the Students' Registration Committee on exceptional cases was also received, without discussion, on the proposition of Dr. NORMAN MOORE, seconded by Dr. KNOX.

Dental Education and Examination.

Mr. C. S. TOMES, in bringing forward the report of the Dental Committee, said that the Council had been approached by a number of embassies or ministries of foreign countries and by the representatives of the colonies asking the Council to make an important departure from previous practice. They had requested that the dental registers of these foreign countries and colonies be accepted *en bloc* by the Council; in other words, that an entry upon those registers should carry the right of entry upon the Foreign or Colonial List of the British Register. That course had never been followed by the Council, largely on the ground that admission to those registers might have been secured under various conditions; in fact, in one of the registers they had discovered 12 different grounds on any one of which people might get on to the Register. The Council had always taken the view that not a mere inscription upon a foreign or colonial register should qualify for admission to the British Register, but only that the courses of training and examination tests should be roughly equivalent to those obtaining in the United Kingdom. The Dental Committee now recommended the Council to keep to this practice and to refuse *en bloc* admissions. One reason that had influenced the Committee was that the Departmental Committee, recently appointed to consider the alleged shortage of qualified dentists, would shortly issue its report, and the present, therefore, was not an opportune moment for the Council to depart from any previous practice. He brought forward recommendations relating to Belgium and to Japan. The recommendation with regard to Belgian dentists was that a request for the Belgian Register to be recognised *en bloc* be not acceded to. This having been agreed to, he moved a further recommendation in the same terms with regard to the Japanese Register, with the addition, however, that the diplomas granted by the Nippon Dental College and the Tokyo Dental College be recognised as admitting to the Foreign List of the British Register. He said that the Tokyo College claimed 66 per cent. of the dental list of Japan, so that in recognising this they were recognising a material part of the Japanese Register.

Sir ARTHUR CHANCE seconded the recommendation, which was adopted.

Mr. TOMES brought forward a further recommendation that the request for the recognition *en bloc* of the New Zealand Register be not acceded to. This request was by the Deputy Director of Dental Services in the New Zealand Expeditionary Force, Major Rishworth, and had been forwarded through the Colonial Office. The Council already admitted one New Zealand diploma—the B.D.S., U. New Zealand degree—as qualifying for the British Register. It was stated, however, that this diploma only included 10 per cent. of the dentists of New Zealand. A letter setting forth reasons for not immediately granting the request had already been sent, but another answer, setting out very fully the reasons why this was not an opportune time for making the alterations suggested, would have to be sent later.

The recommendation was agreed to, as was a recommendation acceding to a request by one dentist to be admitted to the Foreign List on the ground that he entered the Dental College of the University of Michigan in 1891, obtained the D.D.S. Michigan in 1894, and had for 22 years

practised in Dublin. The degrees of the University of Michigan were recognised for registration here up to 1893, when recognition was suspended.

Mr. TOMES also stated that the British Dental Association had expressed its regret at the action of the Council at the May session in approving the scheme of the Birmingham Education Authority for the training and employment of dental nurses. The Representative Body of the Association believed that the approval had conveyed to the public the impression of some recognition of unqualified practice. The Council in giving its approval to the scheme had, of course, made it plain that such dental nurses must be thoroughly under the supervision of registered practitioners. The committee was unable to recommend the Council to make any alteration in its previous resolution.

The Council adopted a recommendation that every person whose name was entered for the first time in the Dentists Register should be entitled to receive a copy of the Register.

After votes of thanks to Dr. Norman Moore for ten years' assiduous service as Chairman of the Business Committee and to the President for his conduct of the chair the session closed.

URBAN VITAL STATISTICS.

(Week ended Dec. 7th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 28·6, against 36·3 and 36·5 per 1000 in the two preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 26·0, or 6·8 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 11·6 in Portsmouth, 12·7 in East Ham, and 12·8 in Enfield, to 53·4 in South Shields, 54·9 in Rochdale, 63·9 in Warrington, 65·6 in Nottingham, 70·5 in Walsall, and 91·6 in Sunderland. The principal epidemic diseases caused 154 deaths, which corresponded to an annual rate of 0·5 per 1000, and included 49 from infantile diarrhœa, 42 from diphtheria, 25 from whooping-cough, 19 from scarlet fever, 18 from measles, and 1 from enteric fever. Scarlet fever caused a death-rate of 1·2 in Birkenhead. The deaths from influenza numbered 3574, against 5119 in the previous week, and included 660 in London, 276 in Birmingham, 254 in Manchester, 172 in Sunderland, 162 in Nottingham, and 97 in Sheffield. The 1099 cases of scarlet fever and 1028 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 37 below and 14 above the respective numbers remaining at the end of the previous week. The causes of 79 deaths in the 96 towns were uncertified, of which 11 were registered in Birmingham, 9 in Liverpool, 6 each in Nottingham and Manchester, and 5 each in St. Helens and Sunderland.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 19·8, against 24·3 and 23·7 per 1000 in the two preceding weeks. Of the 911 deaths from all causes, 24 were classified to influenza, which was also stated as a secondary cause in 165 deaths classified to other diseases; in the previous week these numbers were 47 and 212 respectively. The 376 deaths in Glasgow corresponded to an annual rate of 17·6 per 1000, and included 7 from whooping-cough, 3 each from diphtheria and infantile diarrhœa, and 2 from enteric fever. The 131 deaths in Edinburgh were equal to a rate of 20·5 per 1000, and included 4 from whooping-cough and 1 from infantile diarrhœa.

Irish Towns.—The 172 deaths in Dublin corresponded to an annual rate of 22·5, or 3·5 per 1000 below that recorded in the previous week, and included 42 from influenza, 5 from infantile diarrhœa, and 1 from diphtheria. The 314 deaths in Belfast were equal to a rate of 41·7 per 1000, and included 3 from infantile diarrhœa, and 1 from scarlet fever.

UNRECORDED BIRTHS.—Writing to the Worthing corporation about the incomplete notification of births, the Local Government Board suggests that fathers should be prosecuted, and if this does not result in a considerable improvement in the proportion of births notified, proceedings should be taken against all persons liable—that is, father, doctor, and midwife.

NOTIFICATION OF INFLUENZA IN BELFAST.—At a specially summoned meeting of the Corporation of the City of Belfast, held on Dec. 7th, a resolution was passed unanimously ordering that the Infectious Disease (Notification) Act, 1889, should apply in Belfast for the disease known as "septic pneumonia" for the six months to end 14th June, 1919. In the discussion which took place it was stated that the drivers of the tram-cars (motor-men) had suffered from influenza in a larger proportion than conductors, although the latter were necessarily in closer contact with passengers in crowded cars than the former, who were standing out in the open air. Some of the speakers said it was all very well to make the disease notifiable, but how were they going to cure and to prevent it; others urged that the malady should be made permanently notifiable, but it was shown that it could be made notifiable at any time, subject to the approval of the Local Government Board, by giving fourteen days' notice through a resolution in the City Council.

The War and After.

THE CASUALTY LIST.

THE names of the following medical officers appear among the casualties announced since our last issue:—

Died of Wounds.

Capt. N. K. Foster, R.A.M.C., was educated at University College, London, and qualified in 1908. Prior to joining the R.A.M.C. he was in practice at Oxford.

Died.

Lieut.-Col. C. D. H. Corbett, Royal Air Force Medical Service, was educated at Oxford University and at St. Thomas's Hospital, London, and qualified in 1908. Prior to the war he was in practice in Welbeck-street, London, specialising in dermatology, and contributed many articles to medical literature. He died at Felixstowe of influenza.

Capt. W. R. O'Keefe, R.A.M.C., qualified in Ireland in 1912, and prior to joining the R.A.M.C. was in practice in Sheffield.

Capt. W. H. Compton, R.A.M.C., was a student at Charing Cross Hospital, London, and qualified in 1886. He held appointments as medical referee to several assurance companies, and was at one time a surgeon to the Royal West Indian Mail Steam Packet Co. He died of pneumonia.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Second Lieut. A. B. Beesley, R.A.F., died of pneumonia, second son of Dr. C. Beesley, of Exmouth.

Capt. D. N. Carr, S. Persian Rifles, died in Persia of pneumonia, only son of Dr. D. W. Carr, of the Church Missionary Society, Ispahan.

Able Seaman G. M. Davis, *Benbow* Battalion, R.N.D., died in Holland of septic pneumonia, second son of Temp. Capt. G. W. Davis, R.A.M.C., of Sidcup, Kent.

Second Lieut. F. Sansom, killed in a bombing raid over Germany, third son of Dr. C. L. Sansom, C.M.G., of Kuala Lumpur, F.M.S.

Capt. W. R. Bruce-Clarke, R.A.F., died of pneumonia following influenza, only son of the late Mr. W. Bruce-Clarke, of Harley-street, London, W.

OBITUARY OF THE WAR.

PATRICK JOSEPH O'REILLY, L.& L.M. R.C.P. & S. IREL.,

MILITARY CROSS,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain P. J. O'Reilly, who was killed in action in France on Oct. 11th, was eldest son of the late John O'Reilly, J.P., of Strabane, Ireland. Educated at St. Columb's College, Londonderry, where he was distinguished in the playing fields, at Black Rock College, and at the Royal College of Surgeons in Ireland, he qualified in 1914, and was appointed ship's surgeon on the Blue Funnel Line. Arriving home from China at the beginning of October, 1914, he obtained a commission in the R.A.M.C. and went to France with his regiment, the 9th Devons. In the fighting around Hulluch in September, 1915, he was wounded in the leg, and later gained the Military Cross for conspicuous bravery and devotion to duty, remaining at his post although himself wounded. In May last he was badly gassed, losing his sight completely for several weeks. He met his death whilst tending the wounded. Captain O'Reilly married in 1916 Sybil Olive, daughter of John Collins, of Romsey, Hants. The photograph which we give of him has been enlarged from a snapshot.

THOMAS RICHARD BEALE-BROWNE, M.R.C.S. ENG.,

WEST AFRICAN MEDICAL SERVICE.

Mr. Beale-Browne, who was drowned by the collision of the *Burutu* with the *City of Calcutta* within a few hours of reaching port on Oct. 3rd, at the age of 40 years, was the eldest son of Colonel Beale-Browne, of Andoversford. Educated at Dean Close School, Cheltenham, he proceeded to Guy's Hospital, where he qualified in 1901. He was a keen athlete, taking prizes for running in the Inter-Hospital Sports. Afterwards he made his mark in rifle-shooting, taking prizes at meetings of the Society of Miniature Clubs and at Lagos. After a few years spent in lunacy work at Taunton and the County Asylum, Northampton, he entered the W.A.M.S. On his first tour in 1907–08 he accompanied the Anglo-German Boundary Commission, and afterwards did good work as medical officer in various districts of West Africa. While stationed at Yaba he carried out research work on leprosy. In several cases he noted improvement as the result of his treatment, and in one case apparent cure, but he never afterwards had an opportunity of continuing this work.

Mr. Beale-Browne was a man who put his whole heart into his work, and had the trust and respect of all who came in contact with him. At the time of his death he was homeward bound from the Cameroons, where he had done duty for 21 months. He married in 1910 Helen H. Hay, daughter of the late Donald MacDonald, of Edinburgh, who survives him.

LAWSON TAIT McCLINTOCK, M.B., CH.B. EDIN.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain L. T. McClintock, who died on Nov. 11th at the age of 39 years, was younger son of the late Dr. J. R. McClintock, of Church Stretton. Educated at Shrewsbury and Edinburgh University, he took the M.B., Ch.B. degrees in 1901, and after qualifying filled the post of assistant house surgeon at Salop Infirmary. Settling in Loddon in 1902, he was appointed medical officer to the rural district council and later to the Loddon and Clavering union. At the outbreak of the war he organised the Red Cross Hospital at Loddon and held the post of medical officer there, as well as at the Red Cross Hospital at Hedenham. In 1917 he was appointed medical officer to the 342nd Brigade, R.F.A., and was gazetted captain in the R. A. M. C. in 1918. His death was caused by pneumonia following upon an attack of influenza.

Captain McClintock lived a very active life, took a keen interest in local affairs, and his early death is felt as a calamity. He married in 1903 a daughter of the Rev. S. Irvine, of Londonderry, and leaves a widow and four children.

PHTHISIS IN FACTORY AND WORKSHOP.

To the Editor of THE LANCET.

SIR,—In his interesting article on the prevalence of pulmonary phthisis in relation to industrial conditions (THE LANCET, Nov. 9th) Professor Benjamin Moore affirms the two main factors to be: long-continued working strain and case-to-case infection in unhealthy workshops. I should like to ask Professor Moore, What about the wives of these tuberculous men? Are they not in more unhealthy conditions in their homes? Are not these homes even more ill-ventilated, ill-cleaned, ill-illuminated than the workshops? Are the women not just as much over-strained by domestic work? Moreover, if tubercle bacilli can infect the workmen at a range of 2 or 3 feet in the workshop, surely the same bacilli must be twenty times more infective to the wife of the tuberculous man at point-blank range?

The cause of the different incidence as between men and women must, in fact, be looked for elsewhere, in what French pathologists have long called the *terrain*. It is the individual resistance that counts. Professor Moore records the fact, observed by my friend Dr. Ed. Bertholet, of Lausanne, that up to the age of 25 years more females than males die of tuberculosis. Dr. Bertholet adds that these deaths are largely of abstainers and suggests hereditary tuberculosis as the cause. After 25 years of age more men than women die of tuberculosis, or, as Dr. Bertholet puts it, more drinkers than abstainers. Professor Landouzy said long ago, "L'alcool fait le lit de la tuberculose." Professor Moore has made observations on the printing trade, in which, as Dr. W. C. Sullivan has set out, the average conditions of employment promote industrial alcoholism. No doubt the alcoholic atmosphere of the metropolis contributes to this result. On the other hand, in the country men are scarcely more infected than women. This is in accord with the different conditions of rural life in that (1) the men are seldom exposed to infection and (equally with the town areas) not more than their wives; (2) they lead a healthy outdoor life; (3) they are occasional, not regular, drinkers. Thus the essential cause of adult tuberculosis—alcoholism—is lacking in the case of the rural male. Pathologists tell us that 93 per cent. of the hospital population show at death signs of tuberculous lesions in the lungs, active or healed. This means that practically everyone in poorer urban areas has been exposed to tuberculous infection, but probably at least three-fourths of these infections heal without giving rise to much disturbance of health; only the chronic drinker and the predisposed develop severe disease.

True we must, with Professor Moore, try to stop the contagion in the workshops. But we must at the same time tell the workmen this is only one part of the scheme, and the worker's part is to put an end to the chronic alcoholism.

I am, Sir, yours faithfully,

M. F. BOULENGER,

Ex-Assistant Medical Officer of the Tuberculosis Dispensary "Albert Elizabeth" of Brussels; Assistant Medical Officer, Darenth Industrial Colony.

Dartford, Kent, Dec. 6th, 1918.

THE AMBULANCE DEPARTMENT OF THE ST. JOHN AMBULANCE ASSOCIATION.

To the Editor of THE LANCET.

SIR,—I notice that your reference to "First Aid in Ordinary Life" in your issue of Nov. 30th has been followed by a letter from Sir Rickman J. Godlee and Sir James Cantlie, K.B.E., a Knight of Grace of the Order of St. John.

I feel I must call attention to the fact that the St. John Ambulance Association is the pioneer of voluntary ambulance work, having been formed so long ago as 1877. This fact is, however, already well known, and I wish to refer more particularly to the need for maintaining or acquiring a knowledge of first aid. As Sir Rickman Godlee says, you rightly emphasise its importance, but he is inclined to think that with the advent of peace there will be a falling off in the attendance at classes of instruction. This ought not to be the case, especially if the public can be made to realise

that with the advent of peace their responsibilities are increased owing to the return of so many maimed and crippled prisoners and those utterly wasted and permanently ruined in health.

It will be our duty to attend to the wants of all such persons, and the importance of possessing a knowledge of first aid cannot be exaggerated or too often brought before the public. I am, Sir, yours faithfully,

RANFURLY,
Director.

St. John's Gate, London, E.C. 1, Dec. 11th, 1918.

*** Nothing was further from our desire than to belittle in any way the St. John Ambulance Association, whose service has been regularly noticed in these columns.—ED. L.

THE ABDERHALDEN REACTION.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Nov. 2nd there is an annotation dealing with Dr. J. M. Retinger's investigations on the detection of organic brain tumours by means of the Abderhalden's dialysis method, and the conclusion is reached that "in some hands, at any rate, the method may come to possess a more than academic value." In THE LANCET of Jan. 16th, 1915, I published the results of my clinical investigations based on the methods of Abderhalden. On a series of tests conducted with both the dialysis and the polariscope methods I came to the conclusion that in pregnancy, as well as in cases of malignant disease and many other morbid conditions, proteolytic and peptolytic ferments are present in the blood serum which cannot be demonstrated in the blood of a healthy person. On the other hand, I was unable to find the *specific* ferments claimed by Abderhalden and many of his followers.

Were it actually possible to demonstrate the presence of specific ferments in the blood serum the Abderhalden test would have to be considered as the greatest and the most useful discovery ever made in the domain of medical science. It would only require to devise a routine laboratory test for the purpose of establishing a diagnosis of any diseased condition. Nearly four years have passed since I published my results, and still we do not see this test introduced as a routine examination in the clinical laboratories all over the world. How is it to be explained? The complicated technique is certainly not at fault. No doubt a certain skill is required, but nothing beyond the power of an average laboratory worker. The explanation, I think, is a different one. The test is not generally applied, because it is *of no use for clinical purposes.* It is, in fact, not a clinical test at all. The whole history of the Abderhalden discovery is that of a great scientist who comes out prematurely with a statement, sticks to it, tries to find more and more proofs for its authenticity, and by his personal influence induces many others to repeat his assertions. Over 300 separate investigations were published before I communicated the results of my own work, the great majority confirming Abderhalden's results. Only a few recorded results differ from those of Abderhalden. But in this case time has amply proved that these few and not the majority of workers were right.

I am, Sir, yours faithfully,

J. O. GAVRONSKY.

Cambridge-terrace, Regent's Park, N.W., Dec. 9th, 1918.

ADVANCES IN THE TREATMENT OF FRACTURES.

To the Editor of THE LANCET.

SIR,—Not long ago I had the opportunity of seeing something of the work being done at No. 8 Stationary Hospital, Wimereux, under the surgical charge of Major M. Sinclair, R.A.M.C. I had already had the advantage of learning a little about the sound principles which govern his practice in the treatment of fractures, simple and compound, and of the ingenious methods and mechanical aids which he has elaborated for the management of the most difficult of such cases, for Major Sinclair visited the Queen Alexandra Military Hospital and at the Census Hospital, at which I was then surgical specialist, gave several admirable and instructive demonstrations of his particular technique and apparatus. These methods and their results may be seen on a large scale in No. 8 Hospital, and I can strongly advise anyone concerned with the management of bad fractures to go there, where he will be well repaid by what he can learn. I suppose one is not very far from strict accuracy if one admits that the Thomas splint has been the greatest mechanical non-operative advance in the treatment of fractures which any one man has added to our surgical equipment, and above all to military surgery, where bad cases have to be moved over long distances. But I think I may fairly add to this glorification of the Thomas splint that the clever and practical adaptations of it to the many varied forms of smashed limb in the hands of Major Sinclair, as well as his own particular uses of glue, suitably contrived foot-pieces, and his various methods of extension of limb and retention of fragments in position, make up a contribution to the surgery of the war which is unique and of distinguished excellence. The work of this officer has, in my judgment, diminished suffering, shortened treatment, saved money, and often life itself, and all this perhaps to a greater extent than has been attained by the labours of any one man in the more purely technical branch of our art. I confess myself deeply in his debt for what he has taught in these matters, and on the eve of my return to Australia I feel myself constrained to write this letter of appreciation in the hope that it may impel others to go and see for themselves how great have been the advances in a branch of difficult surgery which we owe largely to Major Sinclair's originality and patient industry.—I am, Sir, yours faithfully,

R. SCOT SKIRVING,
Honorary Major, Australian Army Medical Corps; late Surgical Specialist to the Census Division, Queen Alexandra Military Hospital, Millbank.

London, Dec. 7th, 1918.

DISPENSARY SUPERVISION IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I agree with Dr. G. Jessel (THE LANCET, Oct. 26th) that dispensary treatment is the most economical and best method of treating early non-infective pulmonary tuberculosis. My contention, which Dr. Jessel criticises, was that once tubercle bacilli appear in the sputum dispensary and domiciliary treatment, as understood by the Tuberculosis Regulations, are a danger to the community, and very potent causes in maintaining the high incidence-rate of this disease. Dr. Jessel's first paragraph, in which he admits that close supervision is rarely exercised and that the discipline necessary is irksome, spoils his subsequent arguments. The figures he gives of the number of visits paid by his nurses are not impressive. An average of less than five visits a year per patient cannot be called close supervision. In Southampton during 1916 the tuberculosis nurses paid 4008 visits to 274 cases under treatment, whilst in 1917 5171 visits were paid to 315 cases under treatment. The majority of these cases also attended the dispensary twice a week for treatment. These figures improve upon those given by Dr. Jessel, and yet the results observed have totally failed to convince me that in advanced cases this mode of treatment is satisfactory.

Tuberculosis is essentially a house and factory disease, and is spread by unsatisfactory housing and factory conditions. The housing conditions in a town, particularly among the class of people reached by the Insurance Act, are eminently unsuitable for the treatment of an infectious disease. From Dr. Jessel's figures for 1917—his best year—it appears that 29 per cent. of 1615 patients had unsatisfactory bedroom facilities. I should like to know how many of these had tubercle bacilli in the sputum. He states: "In 1917 complete isolation was obtained in over 70 per cent. of 1615 cases of phthisis." Dr. Jessel's optimism is sublime. Did his 70 per cent. of cases stay rigidly in bed in one room without communication with the outside world? Surely, the period of sleep is the least infective time. Does he imagine that *complete* isolation is ever carried out in a private house, or that even fragmentary isolation is possible in 80 per cent. of the houses of the poorer working classes? Again, Dr. Jessel believes that a visit by the tuberculosis officer once in three months (I presume the patient is notified of the visit beforehand), and five times a year by tuberculosis nurses, will prevent infringements of the "discipline which is admittedly irksome." From past sanatorium experience I am unable to support this opinion.

The vast majority of private practitioners, I fear, think differently from Dr. Jessel. In Southampton this matter was brought before a meeting of medical practitioners

From their own observations and from my statements they were so impressed with the dangers of domiciliary treatment that they drew up a resolution to bring the matter before the health committee of the borough. The opinion of the patient "man-in-the-street" is also, I fancy, opposed to the keeping of foci of infection at large in the community. It is easier to limit opportunities for infection than to cure poverty. At a time when extra nourishment and help are most needed by these patients the State fails them. It is difficult to keep up an irksome discipline upon an empty stomach. The observations of Professor Bang upon the elimination of tuberculosis in herds of cattle by the simple expedient of keeping unaffected animals strictly separate from infected ones bear upon the subject under discussion. What is successful in cattle would, if carried out thoroughly, be equally successful in human beings. The segregation of the "open" cases of pulmonary tuberculosis is necessary if this disease is to be stamped out.

In the last report of the Medical Officer to the Local Government Board much support for this view can be found. The report says: "In pulmonary tuberculosis there may be a latent period stretching over years, and cause and effect may be difficult or impossible to connect." This I plead as justification for the present deficiencies in my figures to which Dr. Jessel takes exception.—I am, Sir, yours faithfully,

OSCAR HOLDEN,
Tuberculosis Medical Officer.

Southampton, Dec. 3rd, 1918.

THE LONDON UNIVERSITY ELECTION: A PROTEST.

To the Editor of THE LANCET.

SIR,—I find that Sir R. Douglas Powell, Dr. Sidney Phillips, and Mr. Eccles have circulated a post-card on which they state that "the chance of returning a medical candidate, who is not a graduate of our University, is very remote." As I am the only medical candidate the statement is that my chance is very remote.

That is not political manners. You may say of your opponent that he will ruin the country or that he has ruined his grandmother. But as regards the election itself you treat him with courtesy and suppose that you meet on equal terms. You don't adopt the boastful manners of Homeric heroes or Goliath of Gath before the fight begins. From that point of view it is an impertinence. From another it comes very near to being a lie, for they state as a fact what they cannot possibly know to be true, and the statement is, as far as I can tell, quite unwarranted. I am not relying on medical votes alone. All of us, I suppose, draw our support, at least I know I do, from all faculties. The medical vote alone is not large enough to return a candidate, but if I get a fair share of it I shall, as far as I can see, stand a very good chance. At any rate, I am quite sure they don't know the contrary, and they've no business to state it as if they did. Four days ago I was told by an elector, and an experienced elector too, that Sir Philip Magnus would be at the bottom of the poll, and, upon my word, when I see his committee reduced to such tricks I begin to believe they think so too. The statement has just as much foundation as their own. The truth is that in a constituency like this no one knows what anyone else's chances are. He only knows the cards he holds himself. If there is not a medical member for the University it will be due chiefly to these three medical men.

And why in the world should they single me out for an attack of this kind, who am of their own profession, and a colleague? Why don't they say that Mr. Somerville's or Mr. Nordon's chances are very remote? They know just as little about them as they know about mine and have just as much ground for the statement. But they have no right to say it of anyone, and they ought to be ashamed of themselves. That comes of party.—I am, Sir, yours faithfully,

W. P. HERRINGHAM.

Dec. 8th, 1918.

[ENCLOSURE.]

University of London.—Parliamentary Election.

It is most important at the present crisis not to divide the Coalition vote. The chance of returning a medical candidate, who is not a graduate of our University, is very remote.

It is certain that every vote not given to Sir Philip Magnus may have the effect of helping to secure the return of the Labour-Socialist candidate.

R. DOUGLAS POWELL, M.D.
SIDNEY P. PHILLIPS, M.D.
W. MCADAM ECCLES, M.B., M.S.

THE ELECTION FOR THE SCOTTISH UNIVERSITIES:

THE ACTION OF THE MEDICAL PARLIAMENTARY COMMITTEE.

To the Editor of THE LANCET.

SIR,—We understand that the supporters of Professor W. R. Smith's candidature for the Scottish Universities are stating that Professor Smith was adopted by this Committee as a suitable representative for the constituency.

This is an erroneous reading of the action of the Committee, which has adopted no candidate for any particular constituency. A list has been made of medical candidates for the election now upon us, and these medical men have been approved for Parliament by the Committee in discharge of the responsibility laid upon it by the general meeting of the medical profession at which the Committee was formed. Yours faithfully,

ARTHUR LATHAM,
CHAS. BUTTAR,
Honorary Secretaries, the Medical Parliamentary Committee.

Medical Parliamentary Committee, 20, Hanover-square, London, W. 1, Dec. 10th, 1918.

AGGLUTINATING PROPERTIES OF CERTAIN SERA: A CORRECTION.

To the Editor of THE LANCET.

SIR,—With reference to my paper on this subject which appeared in THE LANCET of Nov. 9th I stated that the strength of *B. paratyphosus A* and *B* were each only half that of *B. typhosus* in T.A.B. vaccine. Lieutenant-Colonel D. Harvey, Royal Army Medical College, has written to me pointing out that the strength of the Army vaccine has been increased since February, 1916, to the following—viz., 1000 million *B. typhosus* and 750 million of each *B. paratyphosus A* and *B*. I am, Sir, yours faithfully,

THOMAS T. O'FARRELL.

University College, Dublin, Dec. 9th, 1918.

THE PENAL POWERS OF THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—From the peculiar source of its authority the General Medical Council is inclined to pay undue deference to charges brought before it by public bodies, and more especially by Government Departments. From my own long experience of the working of the General Medical Council I feel justified in making this serious statement. The recent case of Dr. Flament, in my opinion, condemns the General Medical Council as unsuited for the judicial functions it exercises. I am not going to say whether Dr. Flament is, or is not, guilty of the offence of which the Council found him guilty; I do not know, and neither does the General Medical Council. But surely he was entitled to be judged fairly according to the evidence laid before the Council. The Council found him guilty of either attempting criminal abortion or of obtaining money by false pretences; there was no other conceivable charge before the Council. I will not dwell on the nature of the evidence or the strange way in which it was got up, beyond mentioning that the witness, on whose statement the charge depended, admitted the criminal offence of inciting Dr. Flament to procure abortion, and that the only corroborating evidence—that of her sister—was not very consistent with the evidence she gave. I challenge contradiction when I say that no competent and honest judge could have found Dr. Flament guilty on the evidence laid before the Council in my presence, evidence on which the General Medical Council did, in fact, find him guilty. But, Sir, the Ministry of Munitions was the prosecutor, and consequently the regulations of the General Medical Council as to statutory declarations, and other safeguards properly required by a judicial body with no power to administer an oath, were not insisted on. An adjournment, to give Dr. Flament some chance to disprove the charge suddenly sprung upon him, could not be allowed. It would have inconvenienced a Government Department. Does the medical profession approve? I am, Sir, yours faithfully,

CUSTOS CUSTODUM.

Dec. 9th, 1918.

THE SERVICES.

Col. A. Webb, C.M.G., D.D.G., A.M.S., will succeed Sir John Collie, Director of Medical Services in the Ministry of Pensions, in view of the treatment by the Army Medical Service, for six months from Dec. 3rd, of pensioners and disabled soldiers.

ROYAL ARMY MEDICAL CORPS.

Temp. Lieut.-Col. Sir Hugh M. Rigby (Brevet Lieut.-Col., R.A.M.C., T.F.) to be temporary Colonel whilst specially employed.

The undermentioned relinquish the acting rank of Lieutenant-Colonel on re-posting: Major J. T. McEntire, Capt. S. J. Higgins.

To be acting Lieutenant-Colonels: Temp. Capt. (acting Major) H. K. Wallace, Major and Brevet Lieut.-Col. D. S. Skelton (whilst specially employed), Major J. W. L. Scott and Major A. W. Sampey (whilst in command of a Medical Unit).

Major E. G. R. Lithgow is seconded for service with R.A.F.

Temp. Capt. H. M. Grey to be acting Major whilst specially employed.

P. S. Clark to be temporary Major.

To be acting Majors: Capt. W. P. Croker; Temp. Capts. D. O. Riddel, W. Mason, C. H Haddow, J. M. Moyes, A. Fullerton, T. L. Hardy, A. Leeming, F. K. Kerr, J. J. Gibb, H. L. Neil, C. E. Sundell, W. S. Stevenson, C. F. White.

Temporary Lieutenants to be temporary Captains: A. Leitch, J. Ramsbottom, R. J. Wilson, N. F. Sinclair.

To be temporary Captains: G. Muir, G. W. Thompson, E. D. Townroe (late temporary Captain, Vol. Bn., E. Surr. R.), S. Barron, W. D. Sammon, C. J. A. Woodside, H. G. P. Armitage, E. W. Diggett, A. R. Barlas, H. S. Campion, T. B. H. Tabuteau, J. L. Annan, F. Joyce, R. J. MacMillan, J. M. Taylor, A. W. M. Sutherland, J. Devine.

E. W. Lynch, late temporary Captain, is granted the honorary rank of Captain.

Temporary Captains G. D. Laing and R. S. Scott relinquish the acting rank of Major on re-posting.

To be temporary Lieutenants: C. H. C. Cosens, A. Bevan, C. A. Basker, J. N. Turnbull, W. G. Cook, J. B. Michie, T. M. Walker, W. L. Hogan, C. E. Pengelly, A. Bisset.

A. B. Pastel to be temporary honorary Lieutenant.

Officers relinquishing their commissions: Temp. Capts. E. A. Sanders, A. Leitch, M. J. Casserly, R. C. Smith, H. E. Bloxsome, W Dalgliesh, C. M. Stevenson, J. N. McTurk, G. L. Brunton, H. C. Halsted (on ceasing to be employed at the County of Middlesex War Hospital), R. L. Hutton, J. A. O'Regan, E. S. Hawthorne, H. Galloway, W. Ainslie, H. D. Pollard, G. E. Lockyer, M. Coghlan (on account of ill-health, and is granted the honorary rank of Captain), J. J. Sinclair (on account of ill-health, and is granted the honorary rank of Captain), A. A. Hall, Temp. Hon. Capt. J. Boyd (on ceasing to be employed with Welsh Hospital, Netley); Temp. Lieuts. A. G. Tolputt, N. C. Fischer, A. M. McCormick, B. F. Howlett, I. Clarke, J. J. Pickles, G. A. Valentine; Temp. Hon. Lieuts. L. W. Darrah, V. S. Laurin.

SPECIAL RESERVE OF OFFICERS.

Capt. H. R. Friedlander relinquishes the acting rank of Major on re-posting.

A. J. Clark, late Captain, is granted the honorary rank of Captain.

Lieut. B. W. F. Armitage, from Unattached List (T.F.), to be Lieutenant.

To be Lieutenants: E. S. Davies, P. G. Quinton, and C. G. Coombs (from University of London Contingent, O.T.C.), W. Young, H. Wands, J. P. Kilty, A. S. Strachan, J. S. McL. Gray, and R. P. Smith (from Glasgow University Contingent, O.T.C.), F. Lyth (from Manchester University Contingent, O.T.C.), A. P. McLeod.

TERRITORIAL FORCE.

1st Eastern General Hospital: Officers to be acting Majors whilst specially employed: Capts. J. C. W. Graham and G. S. Haynes.

2nd London Sanitary Section: Lieut A. W. Allison relinquishes his commission on account of ill-health contracted on active service, and is granted the honorary rank of Lieutenant.

1st Scottish General Hospital: Capt. H. E. Smith to be acting Major whilst specially employed, and to remain seconded.

4th London General Hospital: Major (temp. Lieut.-Col.) G. N. Biggs relinquishes his temporary rank, and is now seconded for duty with R.A.F.

4th Northern General Hospital: Capt. (acting Major) H. J. Smith relinquishes his acting rank on ceasing to be specially employed, and remains seconded.

4th Scottish General Hospital: Capt. J. R. Riddell to be acting Major whilst specially employed.

General List.—Capts. (acting Majors) H. H. Robinson and D. H. Scott relinquish their acting rank on ceasing to be employed.

Capt. R. A. Stark to be acting Major while specially employed.

Lieut.-Col. F. E. Fremantle, from Sanitary Service, to be Lieutenant-Colonel.

Majors H. E. Corbin and A. H. Hogarth, from Sanitary Service, to be Majors.

Major (temp. Lieut.-Col.) A. Greenwood, from Sanitary Service, to be Major, and to relinquish his temporary rank.

Major W. E. Miles to be acting Lieutenant-Colonel while specially employed.

Lieut.-Col. C. E. Humphreys, from Sanitary Service, to be Lieutenant-Colonel.

Capt. R. Briercliffe, from Sanitary Service, to be Captain, with precedence.

Capt. (acting Major) J. Dale, from Sanitary Service, to be Captain, and to retain his acting rank.

Capt. (acting Major) S. R. Gibbs to be Major.

Capts. A. W. Hayward and H. J. A. Longmore to be acting Majors whilst specially employed.

TERRITORIAL FORCE RESERVE.

Major H. L. de Legh, from Attached to Units other than Medical Units, to be Major.

ROYAL AIR FORCE.

Medical Branch.—R. C. Fuller, C. Dickson (late temporary Captain, R.A.M.C.), and J. P. Doyle are granted temporary commissions as Captains.

D. C. Farquharson and P. J. Herlihy are granted temporary commissions as Lieutenants.

Dental Branch.—H. N. Hillier is granted a temporary commission as Lieutenant.

OVERSEA FORCES.

South African Medical Corps.—The undermentioned relinquish their commissions: Lieut.-Col. W. B. Skinner. Major W. H. Marwell, Temp. Major A. Liebaert, Capts. K. Bremer, W. Shanks, C. T. D. Urquhart, D. Melville, J. M Macdonald, Temp. Capts. P. A. Green, T. J. W. A. Johnston, J. B. K. Tough; Dental Surgeons: Lieut. W. S. Murdock, Major C. M. Brothers.

To be temporary Captains: A. J. McClymont, H. B. Maxwell, M. Schwartz, R. B. Woolff, L. G. Irvine, J. Harpur, R. Stevenson, W. M. Tough, W. H. Hunter, D. McCully; Dental Surgeons: C. E. Rice, J. Figdor.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—At a meeting of the Royal College of Physicians of Edinburgh, held within the Physicians' Hall on Dec. 5th, Sir Robert Philip was elected President of the College. The following Fellows were appointed to form, along with the President, the Council of the College for the ensuing year, viz.:—Dr. A. H. Freeland Barbour (Vice-President), Dr. T. J. Thyne, Dr. Francis D. Boyd, Dr. G. M. Robertson, Dr. Harry Rainy, Professor J. Lorrain Smith.

ROYAL STATISTICAL SOCIETY.—On Tuesday next, Dec. 17th, Dr. John Brownlee will read a paper on the Biology of a Life Table, 5.15 P.M., at 9, Adelphi-terrace, London, W.C.

LITERARY INTELLIGENCE.—William Heinemann (Medical Books), Limited, will shortly publish a work on "Pensions and the Principles of their Evaluation," by Dr. Ll. J. Llewellyn and Dr. A. Bassett Jones. Translations of the work into both French and Italian are being arranged.

ROYAL ALBERT HOSPITAL, DEVONPORT.—The annual meeting was recently held under the presidency of Vice-Admiral Sir C. F. Thursby. The medical report was satisfactory, and the financial statement showed a credit balance of £331. It is gratifying to see that the financial position of this institution has been greatly improved.

A SERVICE in memory of the authors, men and women, who have laid down their lives in the war will be held in All Saints' Church, Ennismore-gardens, S.W., on Saturday, Dec. 21st, at 3 P.M. The service will be conducted by Canon A. C. Deane, Vicar of All Saints', and chairman of the Incorporated Society of Authors, Playwrights, and Composers. In view of the arrangements for seating, it will be a kindness if those who intend to be present will notify Mr. G. Herbert Thring, Society of Authors, 1, Central Buildings, Tothill-street, S.W.1.

A SPECIALIST'S VISIT TO A MENTAL PATIENT IN AN ASYLUM.—A Divisional Court of the King's Bench has granted a rule against the Commissioners of Lunacy in these circumstances. The brother of a certified patient at a lunatic asylum having desired that the patient should be visited by Dr. Lionel Weatherly as a specialist, the superintendent of the asylum replied that such a visit would be unprecedented. The request, being repeated through the medium of a solicitor, was granted, but neither the superintendent nor the medical man in charge of the patient met Dr. Weatherly, and the case-book and certificate were not produced to him. The visit having proved fruitless, a request for a further visit was made to the Commissioners of Lunacy. This having been refused, an application in the King's Bench for a mandamus followed. A rule was granted against the Commissioners.

DEATH OF CHARLES MAUDE RICHARDS, L.R.C.P. & S.I.—The death is announced of Mr. C. M. Richards, which occurred suddenly on Dec. 4th, at his residence in Cookstown, co. Tyrone. The eldest son of the late Canon Lewis Richards, D.D., Dungannon, and nephew of the late General Maude, Mr. Richards (who obtained the L.R.C.P. & S. Irel. in 1892) was, after qualifying, for a time medical officer in the well-known Bibby Line, plying between Liverpool and Rangoon, and in the British India Steamship Company. Subsequently he began practice in Cookstown, where, as a most courteous and unassuming man, he was very popular with his patients. He was a well-known member of the Masonic Order. The greatest sympathy is felt for his widow, as Mr. Richards was married only in February last. He was buried on Dec. 7th in his native place.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.1.

Tuesday, Dec. 17th.

GENERAL MEETING OF FELLOWS: at 5 P.M.

Ballot for Election to the Fellowship. (Names already circulated.)

MEETINGS OF SECTIONS.

Wednesday, Dec. 18th.

HISTORY OF MEDICINE (Hon. Secretaries—Charles Singer, Arnold Chaplin): at 5 P.M.

Papers:

Dr. Crookshank: Historical Traces of the Present Epidemic (Polio-encephalitis and Poliomyelitis).

Mr. Robert Steele: Egyptian Days, their Origin and their Medical Application.

Friday, Dec. 20th.

ELECTRO-THERAPEUTICS (Hon. Secretaries—Robert Knox, Walter J. Turrell): at 8.30 P.M., at the Actinotherapeutic Department of Guy's Hospital, when the following Short Papers will be read and discussed:—

(1) A Note on the Construction of the Diathermy Machine (with demonstration): by C. M. Dowse, B.Sc., and C. E. Iredell, M.D.

(2) Diathermy in Gynæcological Cases: by G. Bellingham Smith, F.R.C.S., C. E. Iredell, M.D., and A. E. Marsden, Surgeon, R.N.

(3) Personal Experiences of Burning due to Secondary Radiation: by James Metcalfe, M.D.

(4) Diathermy in Diseases of the Eye: by C. Meadows Ryley, Surgeon, R.N., and C. E. Iredell, M.D.

(5) The Diathermy of the Abdomen: by C. E. Iredell, M.D., with a Note by W. H. Barber, M.D., Captain, R.A.M.C.

(6) Diathermy and Fulguration in Malignant Disease: by Philip Turner, F.R.C.S., Lt.-Col., R.A.M.C., and C. E. Iredell, M.D.

CLINICAL

OBSTETRICS AND GYNÆCOLOGY

SURGERY: Members of these Sections are invited to attend the above meeting.

The Royal Society of Medicine keeps open house for R.A.M.C. men and M.O.'s of the Dominions and Allies. The principal hospitals in the metropolis admit medical officers to their operations, lectures, &c. Particulars on application to the Secretary at 1, Wimpole-street, London, W.1.

The Society's Office will be closed the whole of Christmas week except to Military Medical Officers.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Clinics each week-day at 2 P.M., Wednesday, Friday, and Saturday also at 10 A.M.

(Details of Post-Graduate Course were given in issue of Nov. 30th.)

ROYAL INSTITUTE OF PUBLIC HEALTH, in the Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures on Public Health Problems under War and After-war Conditions (each Lecture will be followed by a Discussion):—

WEDNESDAY, Dec. 18th.—4 P.M., Lecture XI.:—Prof. W. R. Smith: The Proposed Ministry of Health.

LONDON HOSPITAL MEDICAL COLLEGE, in the Clinical Theatre of the Hospital.

A Course of Eight Lectures on Psychoneuroses in Peace and War:—

MONDAY, Dec. 16th.—5 P.M., Lecture V.:—Capt. M. Culpin, R.A.M.C.: Schools of treatment. Exorcism; drugs; electro-therapy; persuasion and suggestion (hypnosis); removal of repressions. Present views illustrated by reference to stammering, &c.

TUESDAY.—5 P.M., Lecture VI.:—Capt. M. Culpin, R.A.M.C.: How to avoid the Censor. Word association; direct hypnosis; association on the symptoms; dream analysis.

THURSDAY.—5 P.M., Lecture VII.:—Capt. M. Culpin, R.A.M.C.: Theory of dreams; symbolism, &c.; transference of emotion; latent and manifest content.

FRIDAY.—5 P.M., Lecture VIII.:—Capt. M. Culpin, R.A.M.C.: Revival of terrifying episodes the key to treatment of most War and many pre-War Psychoneuroses. Freud's views as to mechanism confirmed; his motive power (Sex) rarely found in the War cases. The relation of Epilepsy to the Psychoneuroses.

Births, Marriages, and Deaths.

BIRTHS.

BLAXLAND.—On Dec. 7th, at Newmarket-road, Norwich, the wife of A. J. Blaxland (Major, R.A.M.C., T.F.), of a son.

BRADFORD.—On Dec. 2nd, at Churchfield, Acocks Green, the wife of Captain E. C. Bradford, R.A.M.C. (T.F.), of a son.

BROMLEY.—On Dec. 4th, at the Warden's House, Guy's Hospital, the wife of Captain Lancelot Bromley, R.A.M.C., of a son.

BROWN.—On Dec. 3rd, at Bruntsfield-place, Edinburgh, the wife of Major William Brown, R.A.M.C., of a son.

HODDER.—On Dec. 6th, at Harlyn Bay, Padstow, Cornwall, the wife of Major (temporary Lieutenant-Colonel) A. E. Hodder, D.S.O., R.A.M.C. (T.), of a son.

WOODS.—On Dec. 3rd, at Devonshire-street, W., the wife of Captain R. Salisbury Woods, R.A.M.C., of a son.

MARRIAGES.

CHAMBERS—ALDERSON.—On Nov. 30th, at St. Mary Abbots, Kensington, Lieutenant-Colonel Guy Oldham Chambers, R.A.M.C., to Adèle Maude, widow of Lieutenant A. R. Alderson, R.E., of Cirencester.

MACALISTER—STALKER.—On Dec. 7th, at St. Andrew's United Free Church, Edinburgh, Charles John Macalister, M.D., Rodney-street, Liverpool, to Mary Leslie, youngest daughter of the Rev. Professor Stalker, D.D., Aberdeen.

DEATHS.

COSTOBADIE.—On Dec. 3rd, at The Cedars, Midsomer Norton, Hugh P. Costobadie, F.R.C.S., aged 38.

DAVIS.—On Nov. 2nd, at Delft, Holland, of septic pneumonia, George Makins Davis, A.B., *Benbow* Battalion, R.N.D., in his 23rd year, beloved second son of Dr. G. W. Davis (temporary Captain, R.A.M.C.) and Mrs. G. W. Davis, Dunelm, Sidcup, Kent.

FOSTER.—On Dec. 2nd, on board Hospital Ship *Amara*, Captain Norman K. Foster, R.A.M.C.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

COLONIAL HEALTH REPORTS.

Falkland Islands.—In 1917 the total recorded number of births was 61, of deaths 16, and of marriages 17, as compared with 52, 23, and 29 respectively in the previous year. The birth-rate per 1000 in 1917 was 18·82, and the death-rate 4·93, as compared with rates of 16·14 and 7·14 respectively in 1916. The estimated population of the colony (including South Georgia) on Dec. 31st, 1917, was 3236—2264 males and 972 females. The general health was excellent—better than during the two previous years. Twenty-one cases were admitted to the King Edward VII. Memorial Hospital—12 males and 9 females, 5 of the latter being maternity cases. There were at the end of the year three inmates of the infirmary section (Victoria Cottage Home).

Seychelles.—The Blue-book for 1917 gives the estimated population as 24,528, an increase of 419 as compared with the previous year. The birth-rate was 29·31 per 1000, and the death-rate 20·63 per 1000. The total number of patients treated in the Victoria Hospital during the year was 684; and 3198 patients were treated in the different Government dispensaries. During the last month of 1917 an epidemic of measles of a mild type broke out and continued far into the present year. The principal event of medical interest in 1917 was the return of the Seychelles Labour Force from East Africa in May. The force originally consisted of 791 men; 250 died in East Africa, and it was decided to repatriate the force on account of ill-health. As most of the deaths have been due to dysentery of a bacillary type, which is very virulent and up to that time unknown in Seychelles, steps were taken to quarantine the force on arrival. The general health of the men was then found to be far from satisfactory; the principal diseases were dysentery, pneumonia, malaria, and beri-beri; 25 deaths took place in the quarantine station. At the end of 15 days the acute cases, 15 in number, were removed to hospital and the balance liberated from quarantine. Even afterwards bacillary dysentery broke out in South Mahé in the family of a returned porter, but the prompt measures taken stamped out the disease before it could spread further. Many of the men still continue to have attacks of malaria and several are suffering from septic ulcers which are very resistant to treatment. In all there were 327 deaths amongst the force, a mortality of 41 per cent. A campaign against ankylostomiasis was started by Dr. J. F. Kendrick under the auspices of the International Health Board, and by the end of the year treatment had been accorded to all residents in two-thirds of the Island of Mahé. The campaign is carried out by means of a house-to-house visitation, all who are infected being treated. 90 per cent. of the people have been found to be infected and all classes offered themselves for treatment with great keenness. A law was passed enforcing the provision of latrines on all buildings used for habitation, and this should mitigate the danger of re-infection.

ASCLEPIOS AND ESHMUN.

THE identity of the Phœnician deity Eshmun with Asclepios is assumed as proved in most recent works upon the early history of medicine, and is in agreement with the views of classical authors. There is in existence on a monument an epigraphical record earlier than any classical manuscript, though perhaps not pre-dating the era of the writers, which may be said to definitely decide the matter. This is a trilingual inscription dating from about 180 B.C., proving that, in the opinion of the man who had the text engraved, the deities were varied names for one god. This person was well educated, because he seems to have been conversant with the Punic, Greek, and Hebrew languages. Moreover, he resided in Sicily; therefore, in a country where the facts as to such an identity would be most correctly known.

The inscription referred to may be perused in Vol. I. of the Corpus of Semitic Inscriptions, No. 143, or seen in its present place in the Turin Museum. The Latin and Greek versions are as follows: "Cleon salari(us) soc(iorum) s(ervus) Aescolapio Merre, donun dedit lubens merito merente." "Ἀσκληπίῳ Μηρρὴ ἀνάθεμα βωμὸν ἔστησε Κλέων ὀὲπὶ τῶν ἁλῶν κατὰ πρόσταγμα."

For the translation of the Punic text we quote that of the Rev. G. A. Cooke, M.A. "The lord Eshmun Merre:—the altar of bronze in weight 100 pounds which Cleon of HSGM; who is over the salt mines; vowed; has heard his voice (and) healed him. In the year of the Suffetes Himilkath and Abdeshmun son of Himilk."

This monument was discovered near a thermal spring. In another inscription referring to Eshmun found at Sidon a prince, Eshmunazar, says "he erected a house for that deity near the well of Yidlal in the mountains."

THE "WELLCOME" PHOTOGRAPHIC EXPOSURE RECORD, 1919.

THIS popular and useful little book is at once a guide to photography and a pocket diary for photographers. Having the features of previous editions most things which the photographer requires to know will be found in its pages. The exposure metre on the inside of the back cover has been made more convenient, the correct exposure now appearing opposite each stop. The book should make a useful Christmas present, as the recent withdrawal of restrictions against photography will no doubt lead to a revival among amateurs of this popular art. The price is 1*s.* 6*d.*

WESTON-SUPER-MARE HOSPITAL.

AT a public meeting recently held at Weston-super-Mare it was decided that the war memorial should take the form of a suitable monument and the erection of a new wing to the Weston-super-Mare General Hospital.

AT the last meeting of the Devon education committee it was stated that 27 per cent. of the parents refused to allow their children's teeth to be treated by the dental surgeon. It was suggested that compulsion was necessary, and that the Prime Minister of the new Parliament should be petitioned on the matter.

EDITORIAL NOTICES.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

We cannot undertake to return MSS. not used.

Communications relating to editorial business should be addressed exclusively to The Editor of THE LANCET, 423, Strand, London, W.C. 2

Communications, Letters, &c., to the Editor have been received from—

An Address ON LETHARGIC ENCEPHALITIS.

Delivered before the Medical Society of London on Dec. 9th, 1918,

BY E. FARQUHAR BUZZARD, M.D. OXON., F.R.C.P. LOND.,

TEMPORARY COLONEL, A.M.S.; PHYSICIAN TO OUT-PATIENTS, ST THOMAS'S HOSPITAL AND NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, ETC.

MR. PRESIDENT AND GENTLEMEN,—A great deal has already been written and said about the epidemic of encephalitis which prevailed in this country during the spring and summer of this year. As a result of your personal observation and of reading what has been written by others you are doubtless fully acquainted with the outstanding features of the disease as it presented itself in its characteristic form. I should probably be wasting both your time and my own by describing its ordinary clinical manifestations, or even by describing once again the pathological appearances which have been observed in fatal cases.

When an epidemic of this kind occurs, and when its immediate results and effects have been thoroughly studied, it is well worth while to collect the facts which have come to our knowledge and to see how far they are of practical importance and how far they may be able to throw light into corners of pathology which hitherto have been poorly illuminated. It appears to me that this epidemic has taught two lessons, both of which should be of value to the medical profession, and one of which is very instructive to those of us who are especially interested in neurological problems.

A MEDICO-LEGAL CASE.

In the course of my practice I have been struck on many occasions by the fact that the medical profession has never sufficiently realised that encephalitis, or inflammation of the brain, is a condition which is by no means uncommon, and, if you will allow me, I will tell you a story to support this contention.

Some years ago I was asked to examine a lad of 14 on behalf of an insurance company in regard to what was alleged to be the effect of an injury arising out of his employment. The facts, which were admitted on both sides, were briefly as follows. This lad was employed in doing odd jobs by a builder, and it so happened that on one occasion he was told to carry a hod of mortar up a few steps, which he did without difficulty and without immediate consequences. He was a big, strong lad of 14, and the hod of mortar only weighed a few pounds, but it happened that in the course of the next 24 hours the boy became ill, developed a temperature, suffered from severe headache and vomiting, became delirious and unconscious, and at the end of a few days' illness was found to be completely paralysed on the left side of his body. The acute symptoms rapidly passed off, the hemiplegia cleared up to a certain extent, but the arm was so badly paralysed that it was practically a useless limb. This occurred in the month of October, and some months later I was called upon to give evidence in a county court on the question of whether the boy's hemiplegia was the result of an injury or whether it was due to natural causes. The case was tried by a judge, with the assistance of a medical assessor, and I put forward the view that this was an ordinary case of encephalitis, occurring during the season when encephalitis is usually prevalent, and attacking a young subject, as it usually does. The medical assessor began by asking me what encephalitis was, and I told him that it was an inflammation of the brain. He then asked me what was the cause of the inflammation, and I explained that as far as our knowledge went the cause of this form of encephalitis was a microbe identical with that which causes poliomyelitis, and I gave him some of the facts known to us which supported this view. That my explanation did not convey very much to his mind was shown by his next question, which was: "How do you account, Dr. Buzzard, for the microbe being on the spot exactly at the right time?" It is needless to add that the verdict was against the insurance company, and that the paralysis was judged to be the result of an injury.

ENCEPHALITIS DUE TO THE VIRUS OF POLIOMYELITIS.

But there is another way in which one realises that the diagnosis of encephalitis, especially in regard to the diseases of early infancy and childhood, appears never, or very rarely, to be considered as a possibility. We are constantly hearing the story of patients who are brought to us on account of epilepsy, of mental deficiency, or of hemiplegia that their disabilities have dated from an illness occurring in the first few years of life, and on inquiry into the symptoms of that illness one generally finds that a healthy child has been suddenly taken ill with convulsions, fever, vomiting, &c., and that the diagnosis of meningitis, or gastritis, or teething has usually been made. I am quite convinced from my own experience that a large number of cases of epilepsy, of mental deficiency, of hemiplegia, and of diplegia are the permanent results of attacks of encephalitis occurring in early childhood, and that this large group of cases can be properly attributed to the virus of poliomyelitis. It is unnecessary to dwell upon the reasons which support this view, but they are based largely upon the observations which have been made during the epidemics of poliomyelitis occurring in this and other countries, and in which cases where the inflammation has affected the brain are intimately associated with cases in which the inflammation has affected the spinal marrow, and with still further cases in which the inflammation has affected the whole of the central nervous system, as proved by clinical observation and by post-mortem examination. After all, the brain is a large and important organ, and it would be surprising if inflammation of that structure was not of fairly common occurrence. For years I have urged the view that disease of the brain or spinal cord produced by the virus of poliomyelitis should be regarded in the minds of the profession as one of the acute specific fevers, and especially as one of those acute specific fevers which have a special incidence upon infants and children. It is well known that the susceptibility to this infection decreases as age advances, and, personally, I have met with only a few cases after 25 years of age and none after the age of 40 has been reached.

There are other forms of encephalitis which are met with at much rarer intervals. It is an occasional complication or sequela of typhoid fever. It may possibly be produced by the virus of influenza, and, as we have learnt only too well in recent years, it is a common and fatal complication in cases of head injury.

From the ordinary practice point of view, therefore, it is well to remember that there is a form of encephalitis which has the constitutional disturbances, the age-incidence, the seasonal exacerbations, the sporadic and epidemic types and the immunity from second attacks which are shared by measles, scarlatina, and other acute specific fevers, and that it presents an inflammatory lesion of a particular tissue in the same way as typhoid fever, diphtheria, and small-pox display inflammatory lesions of other tissues. This form of encephalitis has been shown to be due to the virus of poliomyelitis, and it should be noted that the disease is an acute one running its course in a few days, but often leaving permanent results in the form of paralyses, mental defects, and epilepsy.

THE RECENT EPIDEMIC.

We must now turn our attention to the consideration of that form of encephalitis which has attracted notice this year, and which undoubtedly is an entirely different disease from the encephalitis I have just referred to. It is true that there have been in the recent epidemic a few cases which have run a very malignant and rapidly fatal course of a few days, but the striking feature of the majority has been the fact that a careful history shows that symptoms have often been present over a period, not only of days, but even of weeks before the intensity of the process has reached its height. A study of the cases also shows that the age-incidence and the seasonal incidence are entirely different from those of poliomyelitis. Putting aside clinical and pathological differences, the epidemiological data collected by Colonel S. P. James are quite sufficient to prove that lethargic encephalitis is a distinct disease.

You will remember that the attention of the profession was drawn to this epidemic[1] by Dr. Wilfred Harris in London and by Professor A. J Hall in Sheffield, and that both these observers were struck by the number of cases brought to their notice suffering from asthenia, lethargy, and disorders of ocular movements such as strabismus, diplopia, nystagmus, and ophthalmoplegia. These were patients suffering

[1] THE LANCET, April 20th, 1918, p. 568.

from encephalitis with its chief incidence on the brain stem.

This important discovery was quickly followed by the realisation that there were other patients taken ill in the same way, presenting the same constitutional disturbances, the same asthenia and lethargy, but displaying no oculo-motor signs or symptoms. On the contrary, they gave us the clinical picture of acute paralysis agitans; the mask-like, expressionless face, the rigid but not really paralysed limbs, the tremor, the posture, and gait of that disease. I shall never forget my first experience in that direction, when I was asked to see a man lying in bed, looking exactly like a patient who had suffered from Parkinson's disease for 10 or 15 years, and was informed that he had been ill a week! Here we had examples of the encephalitis with its chief incidence on the basal ganglia, and in particular, perhaps, on the globus pallidus.

CASES IN WHICH THE CEREBRAL CORTEX IS CHIEFLY AFFECTED.

It is not my intention to dwell further upon these two groups of cases at present. They have been already sufficiently and adequately described. I propose to confine my attention to the consideration of a third group of patients in whom the force of the inflammation was spent upon the cerebral cortex, and who gave rise to considerable difficulty in diagnosis, especially in regard to the possible presence of cerebral tumour, cerebral abscess, or cerebral hæmorrhage. It is necessary to give you quite briefly an account of a few cases if I am to emphasise the lessons which can be drawn from them.

CASE 1.—On April 5th, 1918, I saw, with Dr. Granger Evans, a lady, aged 54, who, on Thursday, March 28th, noticed that her right hand was rather shaky. The next day she went away for the Easter holidays, but returned on the Sunday on account of the uncontrollable jerking of her right arm and hand, which gradually became worse and spread to the whole of the right side. When I saw her on April 5th there was a mixture of clonic and tonic spasm affecting the whole of the right side, with considerable impairment of voluntary movement and more or less complete aphasia. The reflexes on the affected side were of the usual hemiplegia type, whilst those on the left side were normal. There were a few movements noticed in the left arm, but there were no cranial nerve disorders beyond the weakness of the right side of the face. There was no optic neuritis, and nothing in the cardio-vascular condition of the patient to explain the symptoms.

I saw this patient again on April 22nd, and learnt that the movements had ceased soon after my last visit, but that she had become completely hemiplegic on the right side, completely aphasic and incontinent. She appeared to be perfectly conscious although unable to say a word or to make much response to orders. About a fortnight later she was admitted into the National Hospital, Queen-square, where she gradually became more comatose and died on May 9th, exactly six weeks from the onset of her illness. The early stages of this illness were afebrile and no abnormal condition was found in her heart, lungs, or kidneys. During the last few days of life her temperature varied between normal and 102° and at that time there was some albuminuria.

At the post-mortem examination the surface of the brain was noticeable for the presence of some dark reddish-brown staining in the subarachnoid space evidently due to slight hæmorrhage on the surface of the cortex. This was most marked over the parietal lobe on the left side, but there were small patches scattered here and there in other parts of both hemispheres. Sections of this brain presented all the characteristic appearances of a hæmorrhagic encephalitis without the occurrence of any large hæmorrhage.

The notes of the next case are as follows:—

CASE 2.—The case is that of a lady whom I saw on May 6th, 1918, with Dr. T. H. Brown. She was 44 years of age and complained that she had not been feeling well for some time, but had had nothing particular to complain of until Thursday, May 2nd, when she had some difficulty in doing her work owing, as she explained, to a deficiency in her mental grasp. On the following day she displayed some awkwardness and clumsiness in her right hand, and on the third day the whole of the right arm was weak. On this day she had an epileptic attack, involving and confined to the right side of the body, and this attack was repeated at intervals on the Sunday and Monday, with the result that she became more and more hemiplegic, more aphasic, and distinctly drowsy. She vomited on one occasion.

On the Monday evening when I saw her she lay in bed in a lethargic condition unable to speak, but evidently able to understand some commands, and able to indicate when she wanted to perform natural functions. She was taking her food well, and had little or no rise of temperature. On examination I found complete right hemiplegia with the usual reflexes, and I also satisfied myself that there was some right hemianæsthesia and complete right hemianopia. Her condition remained much the same during the next two days, and a lumbar puncture was performed, the fluid removed being at increased pressure but quite clear, and on microscopical examination normal in its cytology. The Wassermann reaction was negative. At this time she appeared to be suffering from severe headache, and on Thursday mid-day she was distinctly more stuporose, had become incontinent, was swallowing with difficulty, and showed some tendency to ptosis in both eyes. For the first time the optic discs showed slight swelling and blurring of the upper and inner edges.

She was obviously suffering from increased intracranial pressure, and it was decided to do a decompression. This was carried out by Colonel Sargent at 10 o'clock in the evening. She was trephined over the left post-central and temporal regions, and as soon as the bone was removed it was noticed that the dura was bulging, very thin, and easily torn. The brain surface presented a dark purple colour through the dura, and on opening the latter there was found great increase of tension. Shreds of recent clotted blood were scattered about, both beneath the dura and in the subarachnoid space. The cortex was hyperæmic and easily ruptured. The post-central vein was firm and thrombosed, and towards the vertex of the hemisphere the brain matter was deeply blood-stained and partly disintegrated. A sample of blood was taken up in a sterilised pipette for culture purposes, but nothing was grown from it. The patient died the following morning and the post-mortem examination was made the next day.

This brain on removal had on casual inspection the appearance of one from a case of cerebral hæmorrhage, but closer investigation revealed the presence of thrombosed veins on the surface of the left hemisphere and one or two patches of what looked like hæmorrhagic infarction on the opposite side. After hardening, sections through the organ showed the presence of widespread encephalitis confirmed by microscopical examination. When I say widespread I do not mean that all parts of the brain were equally affected, and it has been characteristic of most of these cases that the inflammation has been patchy in its distribution, although there has generally been one large focus where the process has been most intense and most hæmorrhagic.

The account I have just given you of this case is particularly interesting when compared with Case 3.

CASE 3.—I saw a gentleman at Reading with Sir Robert Fox-Symons and Dr. W. B. Secretan on July 24th. His age was 58, and he had always enjoyed good health until about three months before I saw him, when he began to show forgetfulness and to do odd things, such as leaving off an article of his usual clothing. About the same time he began to complain of headache. For about a month there must have been some difficulty of sight, as his attempts to play croquet—at which he had been quite good—had become laughably bad. On Thursday, July 18th, he had stayed away from business, not feeling well, and on Saturday he vomited incessantly and complained of severe headache and pains in his legs. His temperature was about 100° on Saturday and Sunday, and on Monday he became distinctly worse, more drowsy, and somewhat aphasic. On this day Dr. Secretan detected right hemianopia.

When I saw him on the Wednesday he was lethargic and obviously very ill. His pupils were active. Both discs were slightly swollen with engorged veins, but no marked neuritis. There was complete right hemianopia associated with object blindness. He was quite unable to name objects, although he seemed to appreciate what they were when he saw them. If a key was put into his right hand he used it in a normal fashion, but he could not name it. When I suggested "key" he appeared to assent. He had obvious difficulty in understanding what was said to him and made mistakes in carrying out orders. His temperature was then normal. There was no actual paralysis, the knee-jerks were rather sluggish, the right being more brisk than the left, and on the right side an extensor response could be elicited. The blood and cerebro-spinal fluid were examined. The blood-count was practically a normal one and there was certainly no marked degree of leucocytosis. The cerebro-spinal fluid contained a considerable quantity of blood and in addition there were some cells showing fatty degeneration which were not of blood origin.

The patient showed no signs of improvement and it was decided that an operation for the removal of pressure should be undertaken. This was carried out by Colonel Sargent on August 1st, when he exposed the brain in the left post-central and occipital regions. Intracranial tension was increased, and the dura before being opened looked plum-coloured and opaque. When incised it appeared that there had been slight patchy hæmorrhage between its layers, and the cerebral surface was stained yellow. Blood was present in small quantities between the dura and the pia mater, here and there as a thin film and clot, elsewhere as darkish fluid blood. The fluid part had evidently sunk down towards the base, for on retracting the lower part of the exposed brain dark blood welled up in considerable quantities. The convolutions were flattened and pale, and here and there there were lengths of thrombosed cortical veins. Just below the posterior end of the first temporal convolution was a spot which showed considerable softening, but there was no evidence of tumour or abscess anywhere.

The patient stood the operation well, but was very restless during the following night and later became almost maniacal. He began to refuse food and his bladder had to be emptied by catheter for a couple of days. The headache was much relieved by the operation, but the patient gradually become more comatose and died about ten days later. There was no post-mortem examination in this case, but I can hardly entertain any doubt as to the diagnosis of lethargic encephalitis in view of the clinical history and of what was seen at the operation.

The details of my fourth fatal case of encephalitis can be given very briefly.

CASE 4.—The patient was a man of about 50 years of age, whom I saw on Sept. 15th of this year with Dr. Harvey Norton. There was a history that early in August when working in a field in the country he had fallen down unconscious, had been delirious for a few hours, was seen by a doctor who diagnosed sunstroke, and that he continued to complain of headache and vertigo. He remained in a stationary condition until about Sept. 13th, when he was seized with very severe pain in the head, had several epileptiform convulsions, and on examination presented evidence of slight hemiplegia and some hemianopia. He was drowsy and difficult to examine, but he showed no signs of cardio-vascular disease and his optic discs presented no change. The urine was normal. He was moved into St. Thomas's Home on Sept. 16th and a lumbar puncture was performed on the same day. Very soon after this operation he had a general convulsion and died quite suddenly.

The post-mortem examination was made the next day, and the pathologist coming away from it told me that he had found a cerebral hæmorrhage. The brain had been cut up, but I was not satisfied that cerebral hæmorrhage was the whole diagnosis, and I removed portions from several parts for microscopical examination. It was noticeable that there were no signs of arterial degeneration from the naked-eye point of view.

DISCUSSION OF CASES.

The story of these four cases, coming so close together, appears to me to be one of unusual interest. You will notice that all four patients were over 40 years of age, but that none of them presented cardio-vascular changes suggesting the possibility of cerebral hæmorrhage as a diagnosis. In none of the four cases did the clinical history conform closely to that of cerebral hæmorrhage, but suggested some more subacute lesion, and naturally gave rise to the question of abscess or syphilitic thrombosis. In all four cases the Wassermann reaction of the cerebro-spinal fluid was negative. The lesson I have learnt from this experience is that patients over 40, and even over 50, years of age may be the victims of encephalitis, producing the general symptoms of hemiplegia, aphasia, hemianæsthesia, or hemianopia. In the second place, I have learnt that a naked-eye examination of a brain on a post-mortem table is not sufficient to discriminate between an ordinary cerebral hæmorrhage and a hæmorrhage which is only an accidental occurrence in the course of an encephalitis. It teaches us that when there are no obvious gross signs of disease in the cerebral arteries to account for a hæmorrhage it is essential that microscopical investigation should be carried out in order to determine the cause for the blood extravasation. Thirdly, we must look on the presence of thrombosed cortical veins associated with hæmorrhage in the neighbouring brain substance as strongly indicative of an inflammatory process.

There is no reason to suppose that lethargic encephalitis is a new disease, and we may justifiably assume that endemic cases occur from time to time. Most of us can recall patients suffering from symptoms of acute or subacute cerebral disease, in connexion with whom a hesitating diagnosis of cerebral hæmorrhage has been made, and others again of whom a diagnosis has never been properly established. This recent epidemic is of practical importance in that it ought to bring the possibility of encephalitis more prominently before our minds in cases of cerebral disease presenting difficulties in diagnosis. At the moment this realisation may not be of much practical importance, because we are not yet in a position to say what is the nature of the infection, or to point to any method of treatment likely to abort or cure the disease. The experience of these four cases, however, leads me to think that operative intervention in the way of decompression is really contra-indicated, in spite of the presence of increased intracranial tension. Three of these patients died partly, at any rate, from hæmorrhage, and it is hard to believe that decompression can be beneficial when this hæmorrhagic tendency exists.

Prognosis.—Further experience may teach us more about the prognosis in this disease. At present we can only say that some cases recover completely, others survive the acute stage, but carry with them in after life permanent defects due to the morbid process, while a certain number die either from toxæmia or hæmorrhage in the acute illness or from some complication following it.

Microscopical study of the pathological lesions which were found in the brains of the patients whose histories I have given shows the remarkable way in which the vessels of the brain react in this inflammatory process. The chief features are: (1) Perivascular infiltration mainly with small round cells; (2) small capillary hæmorrhages which suggest a gradual oozing of blood through the damaged walls of small veins and capillaries; (3) thrombosis of small and middle-sized vessels in different stages of organisation; (4) ischæmic softenings presenting the appearance of the hæmorrhagic infarction which one sees in other organs; (5) subarachnoid hæmorrhages and cellular infiltration of the lepto-meninges; (6) general neuroglial proliferation; (7) changes in nerve cells, in some places showing chromatolysis and in others a process resembling that of coagulation-necrosis.

A case of lethargic encephalitis which died in the National Hospital from the result of bedsores some months after the acute attack also illustrates the permanent changes in the blood-vessels which have resulted from the acute inflammatory process in the earlier stages of the disease.

Finally, I should like to express my indebtedness to Captain J. G. Greenfield, who has prepared many of the sections and taken all the photographs, and to Captain H. B. Weir, who also assisted me in some of the pathological investigations.

Some of the expenses connected with the pathological examinations have been defrayed by the Medical Research Funds.

LETHARGIC ENCEPHALITIS:*

NOTE ON ITS DISTRIBUTION IN ENGLAND.

BY S. P. JAMES, M.D. LOND., M.R.C.S., L.R.C.P., D.P.H.,
MEDICAL INSPECTOR, LOCAL GOVERNMENT BOARD;
LIEUTENANT-COLONEL, I.M.S. (RET.)

IN THE LANCET of Nov. 2nd, p. 590, is a report of the discussion at the Royal Society of Medicine on encephalitis lethargica. Among the contributions was a brief summary, which Sir Arthur Newsholme had authorised me to give, of the results of an inquiry on the disease recently carried out by the medical staff of the Local Government Board, in collaboration with the Medical Research Committee. For the epidemiological section of the investigation the material considered consisted of 107 cases in the London area and 121 cases in the provinces. In the accompanying maps the distribution of the disease is shown, as well as that of "poliomyelitis."

General Distribution.

Of the cases considered in this note one or more were reported from 51 sanitary districts in the following counties: Middlesex, Essex, Surrey, Kent, Oxford, Chester, Norfolk, Stafford, Leicester, Warwick, Wilts, Salop, Derby, Yorks, Lancs, Notts, Durham, Carnarvon, Monmouth. From one or two other counties there were reported a few cases which we did not consider sufficiently typical to be included for consideration here. Except in London, where 55 cases were distributed about evenly over 22 sanitary districts, the number of cases reached double figures in Birmingham, Sheffield, and Leicester only. These observations indicate the wide and sparse distribution of the malady in the country generally.

Local Distribution.

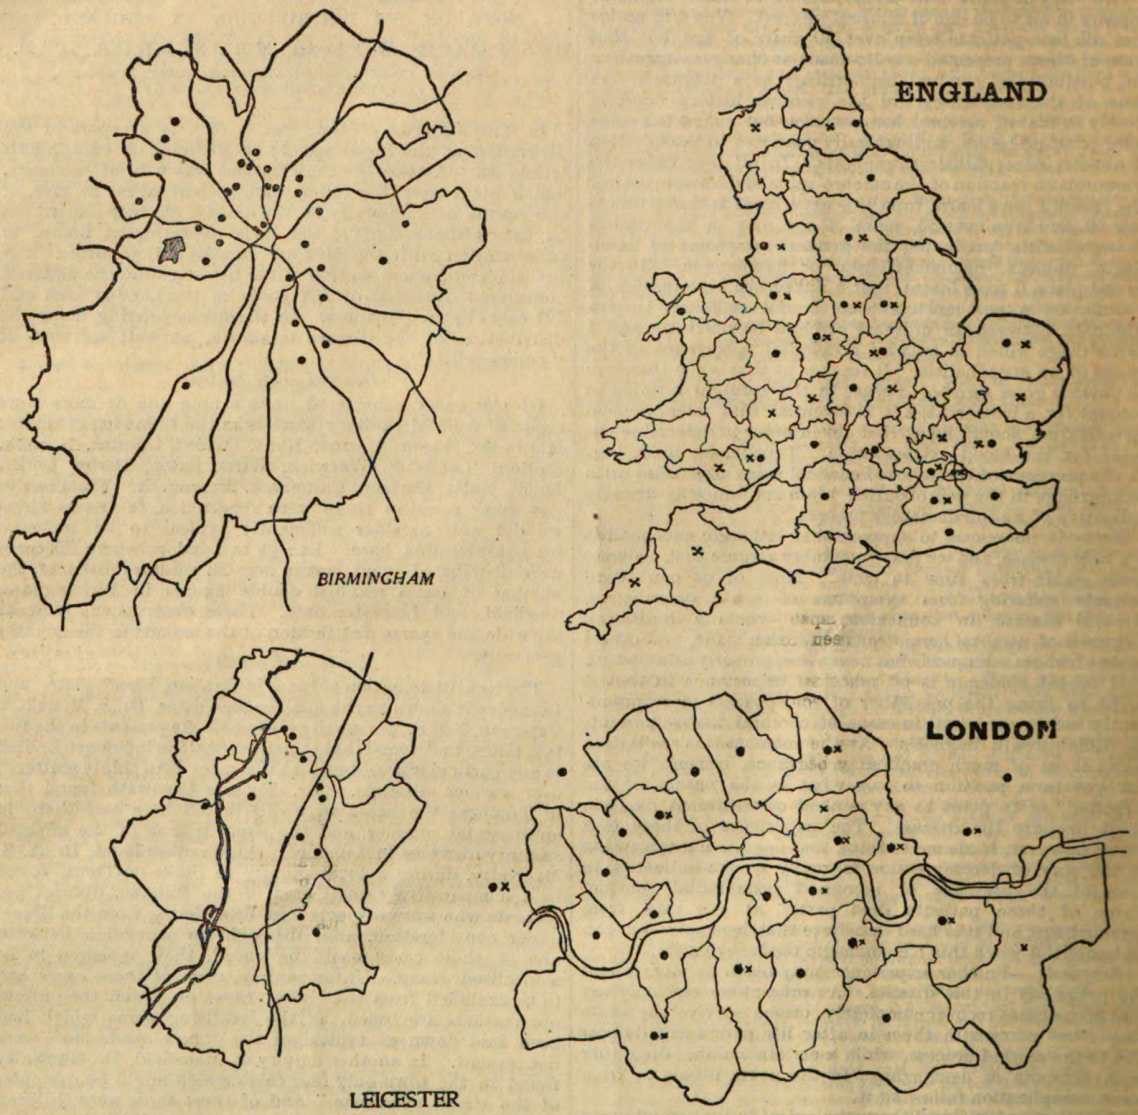
The local distribution of cases in London, Birmingham, and Leicester is shown on the small outline maps. Dr. S. Monckton Copeman, F.R.S., personally visited all the patients in the two last cities, and found that in neither was the incidence limited to any particular area, but that the cases were thinly scattered over various districts. Dr. Thomas Carnwath found that in Tredegar the cases were distributed here and there in an irregular manner, and the same is true in the affected sanitary districts in London. On the other hand, Dr. A. S. MacNalty, during a local inquiry in Stoke-on-Trent, found in a comparatively small area of the Burslem district five patients who were suspected to be suffering from the illness under consideration, and, although no connexion between any of these cases could be traced, they appeared to be a localised group. Unfortunately, three of these cases had to be excluded from the list of cases on which the present observations are based, as the localising signs which had been laid down as typical of the "new syndrome" were not present. In another inquiry at Mansfield, Dr. MacNalty found in the town only four cases which might be examples of the "new syndrome," and of these three were children in the same family. Two of these patients died without any localising signs; the third, who recovered, had slight ptosis, but no ophthalmoplegia. As the differential diagnosis between the "new syndrome" and "poliomyelitis" remained uncertain in all four cases, they were also excluded from the list.

Although careful local inquiries in a number of affected places were made, the observation at Mansfield, just noted, was the only instance in which there was a suspicion of more than one case of the "new syndrome" having occurred in any house or family.

Before comparing the general and local distribution of the illness under consideration with that of "poliomyelitis" for the same period, I may note a general conclusion which seems to be justifiable from the above summary. It is that, having in mind the number of inhabitants in the localities where instances of encephalitis lethargica have been found, it would appear that in all of them the occurrence of a case of the disease is a rare event which, in the absence of a reason for particular search, might pass unnoticed. The summary of distribution shows, however, that in the presence of such a stimulus a few isolated cases having no apparent connexion with one another were discovered almost simultaneously in widely separated parts of the country. This suggests, first, that we have to do with an illness of which

* Summary of a paper read at a meeting of the Royal Society of Medicine.

Outline Maps showing the Distribution of Encephalitis Lethargica and Acute Poliomyelitis.



The dots indicate encephalitis lethargica, and the crosses acute poliomyelitis. In England are shown the counties in which there were cases of the two diseases, while in London this information is given for the sanitary districts.

the sources of origin are indigenous rather than new or imported; secondly, that the outbreak may be one of an unusual number of "sporadic" cases, rather than one brought about by epidemic spread. If this is true it is not surprising that the intensive inquiries made in the affected localities quite failed to reveal the source of origin of any case, or to indicate even a remote connexion between the different cases.

Comparison of the Distribution with that of "Poliomyelitis."

Returning now to the solution of our problem whether the illness is or is not a form of acute poliomyelitis, a comparison of the distribution of cases in the selected groups of the "new syndrome" and of "poliomyelitis" should be of material assistance. The line of reasoning that is justifiable is somewhat as follows:—

(*a*) The illness under consideration has been found to be a severe and often fatal disease. Therefore, if it be a form of acute poliomyelitis it must be a severe and often fatal form such as would not be likely to occur except in places where acute poliomyelitis is prevalent and active.

(*b*) It follows that if we find the "new syndrome" to be prevalent in places where acute poliomyelitis is rare, and especially if it is prevalent in a place where by careful search cases of acute poliomyelitis cannot at the time be found, we may conclude, with a considerable degree of probability, that the "new syndrome" is not a form of acute poliomyelitis.

The following are some results in this connexion:—

1. Between January and June this year cases of the ordinary spinal form of poliomyelitis, with limb paralysis, were officially notified from some 47 sanitary districts. In those districts, therefore, the virus of acute poliomyelitis had not changed its usual pathological effects; and as it had not done so in those districts it is probable that it had not done so in the rest of England.

2. Of the 51 sanitary districts from which cases of the "new syndrome" were reported, there were 26 in which a case or cases of acute poliomyelitis also occurred between January and June this year, but there were 25 in regard to which there was no evidence of the occurrence of a case of that disease.

3. In Stoke-on-Trent, Mansfield, and some other places, special inquiries failed to bring to light that any case of the usual form of acute poliomyelitis had occurred during the six months of the present year; and even in such great cities as Birmingham and Manchester there were only two or three cases in each, and these not in association with the cases of illness under consideration. In London the distribution of the "new syndrome" and of "poliomyelitis" by sanitary districts is shown on the outline map.

On the evidence just presented it appears (1) that cases of the "new syndrome" have occurred in places in which cases of true poliomyelitis could not at the time be found; and (2) that they have occurred in places where the latter disease, though present, has been rare at the time of discovery of the "new syndrome" cases.

THE PRACTICAL SIGNIFICANCE OF THE MASS-REFLEX

IN THE TREATMENT OF INJURIES OF THE SPINAL CORD.

BY GEORGE RIDDOCH, M.D. ABERD., M.R.C.P.,

TEMP. CAPTAIN, R.A.M.C.; MEDICAL OFFICER IN CHARGE, EMPIRE HOSPITAL FOR INJURIES OF THE NERVOUS SYSTEM; ASSISTANT PHYSICIAN TO THE HOSPITAL FOR NERVOUS DISEASES, MAIDA VALE.

IN 1917 a condition was described in certain cases of grave injury of the spinal cord which was called the "mass-reflex."[1] The presence of this widespread reaction introduces many difficulties in the nursing and treatment of the afflicted patients. These, however, can be met if the phenomenon and the principles underlying its production are understood.

I.—*The Phenomenon.*

For a period, varying in uncomplicated cases from a few days to three weeks after the incidence of the spinal injury, the spinal cord distal to the lesion is under the influence of "shock." There are flaccid paralysis of skeletal muscles and loss of sensation in the affected regions of the body. The limbs lie motionless on the bed. The functional activity of all reflex arcs of the isolated segments of the cord is almost completely abolished. There is retention of urine and fæces, due probably, in the main, to tonic contraction of the internal sphincters, which are innervated by the sympathetic nervous system. The skin is dry. This has been called the "stage of flaccidity."[2]

As the effects of spinal shock pass off reflex excitability returns; the paralysed muscles recover tone, the bladder expels its contents at intervals, the rectum becomes automatic in its action, and an area of skin, varying with the level of the spinal lesion, may begin to sweat. This is the "stage of reflex activity."

Now in a well-defined group of cases, especially where the spinal cord has been completely divided, a nocuous stimulus, such as a scratch or a prick, applied to any paralysed part evokes a flexor spasm. This consists of flexion at hip and knee, dorsiflexion at the ankle, and an upgoing movement of the toes, together with flexion of the trunk from contraction of the muscles of the abdominal wall, provided the lesion is high enough. With a stimulus of moderate strength it is, as a rule, bilateral, and if the stimulus is applied to a part in the middle line of the body, such as the penis, perineum, or bladder, both lower limbs flex simultaneously and the muscles of the anterior abdominal wall contract as a whole. Following the spasm the trunk and limbs resume their former posture, not from contraction of the extensor muscles, but from relaxation of the flexors and the action of gravity. So far as the trunk and limbs are concerned, it is a uniphasic movement of violent nature in which the flexor muscles only are actively involved. Moreover, the energy evoked by the stimulus overflows into channels with which the reflex manifestations are not associated normally. Stimulating the sole of the foot aids evacuation of the bladder, and may be followed by an outburst of sweating from the skin over an area corresponding to the level of the spinal lesion. Conversely, automatic evacuation of the bladder or rectum may evoke a flexor spasm. This is the "mass-reflex." Stimuli capable of eliciting it are generally of nocuous character, such as pricking or grasping the limbs; but if reflex excitability is high such gentle stimulation as that produced by light friction or by the removal of the bedclothes may be followed by a flexor movement so sudden and vigorous as almost to jerk the patient out of bed. The parts in which the threshold is lowest are the terminal regions, the soles of the feet, the external genitals, and the anal region.

II.—*The Principles Underlying it.*

One of the dicta of Hughlings Jackson was that in disease there are a negative and a positive aspect. Applied to the cases of injury to the spinal cord under consideration, loss of control of higher centres over the lower centres in the spinal cord corresponds to the negative effect, and the diffuse reflex response corresponds to the positive effect. The presence of this massive reaction indicates a low grade of neural control. A stereotyped set of movements can be evoked from a large receptive field comprising both somatic and visceral regions. There is little tendency to modification in form according to the locality of the stimulus. What Sherrington has called the "local sign" of a reflex is almost entirely absent. The anchored body has one reaction to a nocuous stimulus only, a violent withdrawal from harm. A primitive defensive reaction is all that remains.

Why does this overflow of reflex activity occur in some cases of gross injury to the spinal cord and not in others, although interference with the functions of the cord may appear, at first sight, to be equally severe? There may be complete loss of sensation and of voluntary power in the affected parts of the body in the two groups of cases, and yet in the one the mass-reflex is present and in the other it is absent. On the other hand, the patient may be able to move his limbs in some degree and may be conscious of alterations in the posture of his legs and of other sensory impulses, he may be able to tell with accuracy when his bladder is full, and yet this massive reaction may be evoked on one side and not on the other.

It has been shown[2] that when the muscles exhibit "postural tonus" (Sherrington[3]), and when certain reflex reactions can be elicited, indiscriminate activity in the spinal cord distal to the lesion disappears, and the massive reaction ceases to be obtained with stimuli of moderate intensity. In these reactions extension of the lower limbs, as a whole, can be evoked. When the sole of the foot is scratched there is no longer a violent flexor spasm of the lower limbs and trunk, with evacuation of urine and excessive sweating. The irritated limb withdraws from the nocuous stimulus, it is true, but in a more controlled way; the contra-lateral lower limb extends, and the abdominal wall takes no part in the motor effect. The flexed limb may then extend and the other flex, and so on for some time, the feet moving up and down rhythmically and in opposite phase. These movements resemble closely those of progression. Flexion occurs not only as a simple withdrawal movement, but takes part in a biphasic reaction, which may be the remnant of the ancient mechanism for escape from harm. Further, the amount of moisture on the skin is not altered by the reflex, and the bladder is unaffected. The spinal cord behaves in a more restrained and discriminative fashion. Stimulation of the thigh, or pressure on sole of the foot, is followed by extension of the limb, and not by a massive flexor response, and irritation of the penis elicits a reflex reaction which is adapted to an obvious end.

In a patient in whom these primary extension reflexes can be obtained the nervous mechanism of the bladder and sweating can no longer be influenced by somatic stimuli of ordinary intensity; and, on the other hand, evacuation of urine does not initiate movements in the limbs or trunk.

Control of spread of impulses within the spinal cord is thus associated with activity in the extensor reflex arcs, with biphasic movements of the limbs, and with the presence of "local sign" in the reflexes, by which is meant variation in the reflex manifestation with the locality of the spot stimulated. A higher grade of neural activity is manifest, and what can be interpreted as choice and discrimination becomes evident even at this low evolutionary level of the central nervous system.

In the frog the "centres" of the extensor reflex arcs lie in the spinal cord; in the dog they are situated partly in the spinal cord and partly in the medulla and pons (prespinal). In man the control is relegated in most cases almost entirely to "centres" in the brain-stem, belonging probably to the cerebello-pontine system. I hope, however, to give evidence in a future paper to show how even the isolated spinal cord in man may sometimes resume its ancient postural functions after a long period of freedom from higher control.

III.—*The Practical Significance of the Mass-reflex.*

It becomes a matter of great importance for the comfort and proper nursing of these patients to consider how the mass-reflex affects them.

(*a*) *The bladder.*—The ease with which impulses spread in the spinal cord, influencing all the reflex arcs, is in most ways the cause of great inconvenience to the patient and of innumerable difficulties in nursing. But in the treatment of the paralysed bladder it can be taken advantage of and sometimes a valuable aid.

It is of the utmost importance to stop catheterisation as early as possible, as it undoubtedly forms the greatest risk to infection of the bladder, and the bladder holds the key to life and death for the patient. Every possible precaution should be taken to avoid the dangers of urinary sepsis, and as soon as the bladder has begun to evacuate its contents automatically it follows that if catheterisation can be stopped a great advantage is gained. But at this time the automatic action of the reflex arcs is still imperfect and a residuum is left. This forms a favourable nidus for organismal growth and must be removed. In the mass-reflex we have a solution to the problem. It should be ascertained at what interval the bladder "fires off" in each particular patient. It may be every two hours or every four hours, the time varying considerably in different patients, but remaining fairly constant for each case provided no febrile complication arises. About the time when the bladder is due to evacuate the nurse or the orderly or the patient himself can evoke a flexor spasm by stimulating the abdominal wall or lower limbs. In this way the reflex activity of the bladder is facilitated and reinforced, with the result that all the contents will be voided. The bottle can then be emptied after each act, and the risk of wet beds is thereby greatly diminished. The patient can perform the whole process unaided. Knowing the approximate time at which his bladder is due to "fire off," by squeezing his thighs or pressing on his abdomen he can start off a strong reflex reaction which finally empties the bladder entirely. Thus, he can practically at any time empty his bladder by originating and reinforcing in this way the automatic action of the vesical nervous mechanism.

In bed a glass or enamel urinal is best, as it can be properly cleansed, and if these precautions are taken spilling of urine from the bottle caused by flexor spasms need never occur. This is of great importance, as the skin of the buttocks and limbs soon gets abraded if rubbed against wet sheets, and bedsores already existing are hindered from healing. Control of flexor spasms, which pull the patient about in bed, will be described later. When the patient is getting about in a spinal carriage, but more particularly in a ward wheel-chair or in a hand-propelled chair, a rubber bottle strapped round the waist and with a close fitting tube for the reception of the penis is most serviceable, but it has this disadvantage that it is more difficult to clean than is the bed urinal.

(*b*) *Gastro-intestinal conditions.*—To the uninitiated a group of symptoms frequently complained of by patients with dorsal lesions and due to the mass-reflex may be puzzling. After a day of vigorous flexor spasms or during the administration of an enema or catheterisation of the bladder the patient often complains that the abdomen feels distended and uncomfortable—that is, he is disturbed by feelings of nausea and that he cannot take his food. He begs for relief from what he thinks is flatulence, and the whole Pharmacopœia may be tried without avail. The cause of the abdominal discomfort is not gastro-intestinal irritation, but impulses originating from the flexor spasms spreading and exciting the visceral reflex arcs. Attention must be focussed, then, on the control of the spasms. The enema fluid must be injected slowly so as not to distend the rectum unduly. Cleansing of the penis prior to passing the catheter must be done gently and with a non-irritating antiseptic fluid, such as a very weak solution of eusol (1 in 6000 to 8000). The catheter must be inserted slowly and the penis held gently. Irritation of the external genitals is a potent stimulus for evoking the mass-reflex response. In the glans penis the threshold is almost as low as in the sole of the foot. Patients in whom flexor spasms are evoked with stimuli of low threshold value have to be very carefully handled in bed. The position of the limbs least favourable for involuntary movements must be ascertained by the nurse.

On the other hand, the earliest symptoms of an attack of pyelitis are flatulence with abdominal distension and feelings of discomfort referred to the abdomen; but these symptoms are constantly accompanied by more definite loss of appetite and a white furred tongue, and, if visceral sensibility is not abolished in the affected parts, by tenderness on one or both sides on deep palpation of the renal region. The rectus abdominis on the sensitive side is usually more tense than on the opposite side. These symptoms may be present before a rigor or a definite rise of temperature occurs. Impulses orginating from the irritation of the intestinal tract constantly pour into the spinal cord by way of the visceral afferents and evoke vigorous and frequent spasms of the lower limbs and abdominal wall. At such a time treatment must be directed towards the urinary condition primarily and to the gastro intestinal secondarily. Of course, indiscretions in diet lead to abdominal discomfort and to the initiation of violent flexor spasms, and in consequence have to be carefully avoided.

(*c*) *Sweating.*—Excessive sweating is a prominent and distressing feature of the mass-reflex response. The area of skin from which the sweat pours varies with the level of the spinal injury. For, as has been demonstrated,[1] it is the level at which the connector fibres, forming the communication between the spinal cord and the sympathetic nervous system proper, are shut off from the controlling influence of higher centres by the lesion that determines the sudorific area. The sweating surface, then, is also, physiologically speaking, below the level of the lesion, just as is the area in which sensation is lost. The different extent of corresponding areas is due to the fact that as regards the distribution of the peripheral fibres of the sympathetic system there is no segmental correspondence, whereas sensory and afferent fibres of the posterior roots of the central nervous system are segmentally arranged.

Since the excessive secretion of sweat is one of the trials to which paraplegics who show the mass-reflex are subjected, and since a continual moist condition of the skin greatly increases the liability to bedsores, it is a matter of great importance to find means by which this condition can be controlled. All stimuli which are capable of evoking the mass-reflex excite, with the other components, excessive sweating. The position of the paralysed limbs in bed may be a fruitful source of excitation and will be dealt with in the next section. Gastro-intestinal disturbances have been considered, as also have some aspects of vesical irritation. Rough handling of the genital parts during catheterisation, as when the glans is swabbed too roughly in cleansing or when the penis is grasped too firmly, is a productive source of stimulation. The catheter, too, should be passed gently, and in bladder lavage bland, non-irritating fluids (eusol 1 in 16,000) must be used. If these precautions are taken sweating will be less profuse during the daily bladder manipulation. But it will be found in many cases in which the spinal cord is very sensitive to stimulation that the act of reflex evacuation of the bladder may evoke excessive sweating. During lavage, after the bladder has voided its contents the first time, there may be no increase of the moisture of the skin, but when the reflex act has been evoked several times the patient usually pours with sweat. As a rule, however, it is unnecessary to wash out the bladder by evoking the reflex more than three times in succession.

Heightened intravesical tension, which causes stretching of the bladder musculature, may be the source of excitation of profuse sweating. When the spinal lesion is well above the lumbar enlargement, this cause of irritation is not, as a rule, prominent; for by the time the patient has begun to sweat below the level of the lesion the bladder is automatic, and it is only when there is abnormal spasm of the sphincter induced by cystitis that this complication arises. But when the lesion is situated near the lumbar enlargement the vesical reflex arcs recover their functional activity late, as a rule, so that retention of urine may co-exist with flexor spasms and excessive sweating. In such cases it is of extreme importance that the bladder should be emptied by catheter at regular intervals. Usually, if the catheter is passed every six hours during the period of retention the bladder will never be over-distended, but in many cases the bladder has a smaller capacity than normal, and it must be emptied at four- or five-hourly intervals.

As has been already said, the antiseptic fluid used in washing out the bladder must be as bland as possible. A strong solution of eusol, potassium permanganate, or any other antiseptic has a powerful irritating effect on the mucous membrane of the bladder, whereby its resistance is lowered against organismal infection. At the same time strong impulses, which the caustic fluid initiates, stream into the spinal cord, evoking excessive sweating, flexor spasms, and all the phenomena of powerful mass-reflex reactions.

To find out and to eliminate, as far as possible, the exciting causes of reflex sweating is the most important part

of the treatment of the condition. Drugs frequently have no effect in controlling a profuse sweating, but in some cases atropine will be found to be useful. So as not to dissipate its effect it is best to limit its administration to the evenings, in order to try to control the outpouring of sweat in the night, which so often disturbs the patient's rest. Liq. atropinæ, ♏ i.-ii., given in water about 8 or 9 P.M., will be helpful in many cases.

(*d*) *Flexor spasms.*—The defenceless patient, lying anchored in bed, is at the mercy of the strong involuntary flexor movements of the lower limbs and trunk which convulse him periodically. So violent may these spasms be that he is pulled hither and thither, and may even be thrown out of bed. If the paralysed parts are active and the spasms uncontrolled he gets no peace and life is a misery to him. It is as if he was in the clutch of a powerful enemy who is unrelenting in his tortures. It becomes, then, imperative that the physician and nurse find out how the flexor spasms can be controlled.

These movements form part of the mass-reflex, and impulses arising from stimuli of nocuous nature from any part of the paralysed region of the body can evoke them. Tension on the muscles of the limbs, an over-distended bladder or cystitis, gastro-intestinal irritation, irritating bedsores are all capable of evoking vigorous involuntary flexor movements. The posture in which the lower limbs and trunk are least excitable must be ascertained in each individual case. It will be found, as a rule, when the patient lies on his side with the abdominal muscles relaxed and the lower limbs drawn up that he can get freedom from spasms for a considerable time. Provided that the skin of the buttocks is healthy, and the soft tissues over bony parts are relieved from pressure, it is often advisable to place the patient in this position for the night. Another posture which will be found to give relief is one in which he is propped up in bed in a semi-sitting position, with the legs somewhat flexed and supported under the knees by pillows. The feet are kept up by a foot-rest. A combined adjustable foot-rest and support for bedclothes was devised for use at the Empire Hospital, and has been found of great value.

Nurses who are unaccustomed to deal with patients of this class must be taught how to handle them, for they can do much to alleviate their sufferings by adopting proper methods in turning the patients and moving them about in bed. The paralysed parts have to be manipulated gently and without jerking movements. With a pulley rigged over the top of the bed the patient can do much to help himself, and he soon becomes very proficient in moving his body about.

Urinary sepsis, dyspepsia, and intestinal disturbances are accompanied by frequent violent flexor movements, and with successful treatment of these conditions the spasms diminish in frequency again. Inflammation of the prepuce and of the skin of the scrotum caused by uncleanliness or faulty adjustment of the urinal may be the focus from which impulses pour into the spinal cord. The external genitals should be carefully washed at least twice a day, and the urinal cleansed each time it is emptied. It is often advisable to place a pad of cotton-wool between the urine bottle and scrotum.

The cause of unusual flexor activity in the limbs is sometimes traced to irritating bedsores, especially if they involve the tissues near the feet, where the threshold is low. Sores situated over the sacrum or buttocks are much less potent, for in this region the threshold is high. Superficial healing bedsores and even abrasions of the skin covering the malleoli or the heel are just as irritating as are sloughing, septic wounds; if clean, an ointment containing benzoin or zinc will be found to be soothing, and will at the same time promote healing. If the wounds are septic and sloughing fomentations applied four-hourly till the sloughs have separated is the best treatment. Then, so long as the sore is discharging pus it may be cleansed with eusol, 1 in 6000 or 8000, or liq. sodæ chlorinatæ (B.P.) or liq. aluminii acetatis, 2 per cent., and dressed with gauze wrung out of the solution, morning and evening. When the wound is becoming clean and healthy red granulations are forming, a simple dry gauze dressing can be used. The formation of unhealthy pale granulations indicates that fomentations or antiseptic wet dressings should be stopped. The healing process can then be aided by the application of stimulating solutions, such as red lotion, friar's balsam, or liq. argenti nitratis, 1 or 2 per cent.

It is a mistake to give up large dirty bedsores as hopeless. They will heal in the majority of cases, though the healing process is slower than in normal tissues. If carelessly dealt with they will kill the patient as surely as will a septic urinary tract; and the one condition allows the other to flourish.

The nursing and general treatment of paraplegic patients who exhibit the mass-reflex can be summarised shortly. The spinal cord below the lesion is exquisitely sensitive to impulses originating from the most diverse stimuli. The reaction evoked involves the whole paralysed region, somatic and visceral, and is so uncontrolled and violent in character that it dominates the life of the unfortunate patient. Our endeavour should therefore be directed to allaying the excitability of the spinal cord by removing as many nocuous influences as possible. The limbs and the viscera, such as the bladder and intestinal tract, must be treated with the greatest gentleness, and every care must be taken to avoid the generation of long-continued and violent mass-reflexes.

BLOOD PRESSURE AND PHYSICAL FITNESS OF THE SOLDIER.

BY V. E. SORAPURE, M.B., F.R.C.S. EDIN.,

TEMPORARY CAPTAIN, R.A.M.C.; DEPARTMENT OF TRENCH FEVER RESEARCH, HAMPSTEAD MILITARY HOSPITAL.

IT has been suggested to the writer that a brief note on some blood pressure observations, which have been in the melting-pot for some years, may be of value at the present time.

Description of Test.

Because of the absence, up to the present time, of a satisfactory explanation of the significance of the tonal changes evident in making a blood pressure observation by the auditory method most clinicians have been led to ignore them, and but few in this country have even observed them. The technique is perfectly simple, being well within the capacity of a nurse; and in spite of all that has been written to the contrary, the writer is quite convinced that the subjective factor is no greater than that which enters into the other, more usual, physical tests. Indeed, it is less than in many.

The phenomena observed and the descriptive terms applied are as follows:—

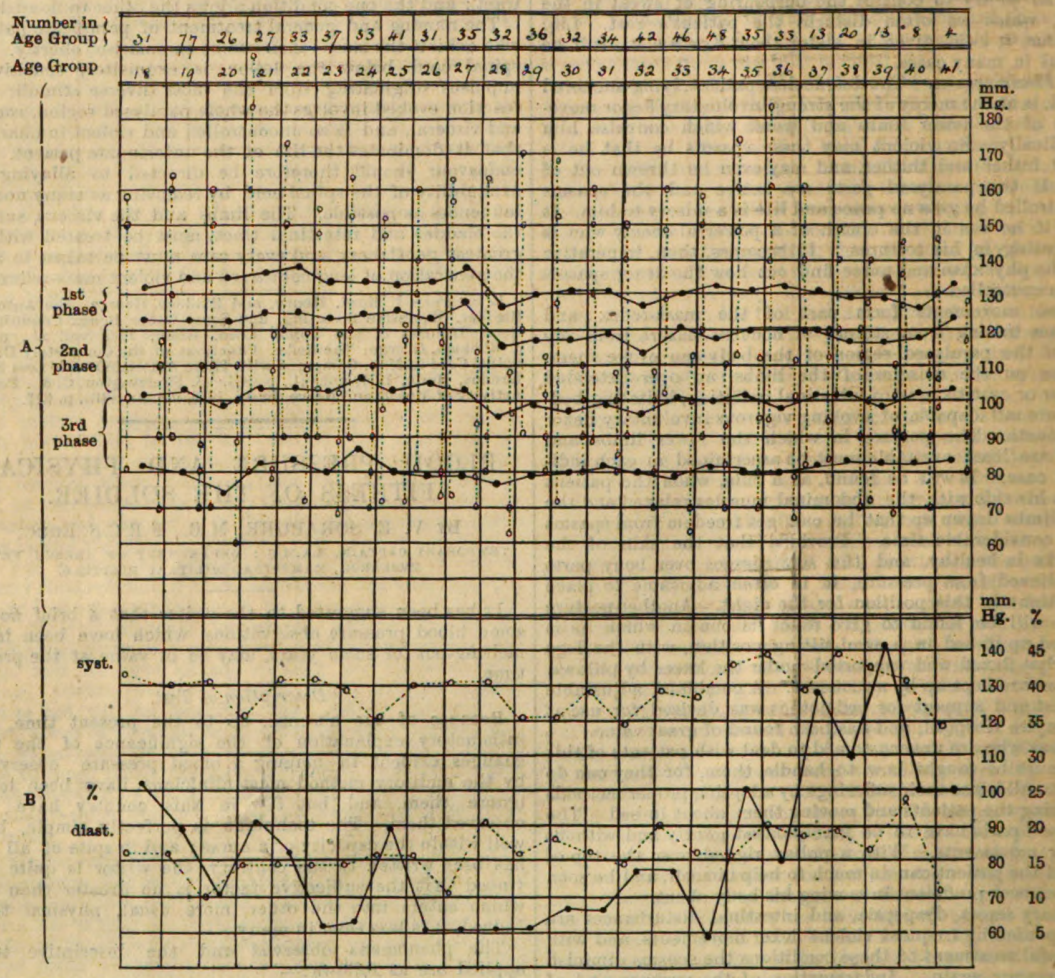
The brachial being compressed with the cuff and the chest-piece of the stethoscope applied over the artery at the lower border of the cuff in the usual way, it will be noted that as soon as the blood re-enters the artery a sharp tap is heard; this is quite generally recognised as indicating the systolic blood pressure. The first tap is followed by a succession of similar taps all in the same tone; this series of taps is regarded as being the *first*, or *first tonal, phase*. Normally this is followed by a series of short murmurs; these last for a variable period as the mercury column falls, and may encroach upon, or be encroached upon by, the preceding or succeeding phase. This murmur phase is usually termed the *second phase*. The *third phase* follows, this is also a tap or tonal phase; the taps follow the series of murmurs somewhat abruptly, and are clearer and more intense than those of the first tonal phase. At a certain point the sharp tap becomes suddenly and definitely muffled; this is the point most generally accepted as representing the diastolic pressure, and the whole series of muffled tones is termed the *fourth phase*. The point at which no sound is audible is the *fifth phase*.

Duration of each phase.—As will be seen later, the first should be 20 per cent. of the pulse pressure, the second 40 per cent., and the third 40 per cent. It may be well to recall that the term pulse pressure means the difference between the systolic and diastolic readings. A reading which showed 120 systolic and 80 diastolic would indicate a pulse pressure of 40, a first phase of about 8, a second phase of about 16, and a third phase of about 16 mm. Hg, and would read thus: 120, 112, 96, 80.

I now suggest that the presence and relative lengths of these phases is of wider clinical significance than the height

TABLE I.—*Giving an Analysis of 769 Blood Pressure Observations in a Group of Guardsmen during their Twelfth Week of Training.*

A, The upper part of the table indicates (dots and lines) the average pressure readings in each group *showing all phases*, and (circles and dashes) the highest and lowest reading in each group.



B, The lower part of the table gives (dots and lines) the percentage of men in each group *ailing to show all phases*, and (circles and dashes) the average systolic and diastolic pressure of those making up this percentage.

of the systolic pressure alone, or even that of the systolic and diastolic readings compared. It is quite a common experience to find an obviously inefficient heart giving what is accepted as a normal systolic and diastolic blood pressure reading. Yet I have not seen a case such as this which showed all the phases in anything like the suggested normal proportion.

Results in Soldiers under Training.

Table I. is an analysis of the blood pressure findings in a group of 769 soldiers (Guardsmen) during the twelfth week of training. The standard set as suitable for the test was that each man selected should be "up to his squad"—that is, he had not fallen back in his training because of any physical disability. The men were examined in small groups at 4 P.M. daily. This time was selected as the object of the test so as to determine the fitness of the men at the close of the day's work and to compare their relative endurance at different ages. Observations were also recorded after exercise; and pulse and respiratory conditions were noted, but these are not considered in this note.

1. Comparison of the age-groups shows that there is but little variation in the average readings, all being much on the same level.
2. The average systolic pressure is higher than that which one finds in the conditions of civil life. It will be remembered that these tests were made at the end of a hard day's work.
3. That the average diastolic pressure is more constant, not showing the same tendency to rise as the systolic.
4. That the average pulse pressure is approximately 60 per cent. of the diastolic pressure.
5. That the average period of the first phase is 20 per cent. of the pulse pressure.
6. That the average period of each of the second and third phases is about 40 per cent. of the pulse pressure.
7. That with the singular exception of age 25, ages 23 to 31 showed the highest percentage of men in whom all phases were present.
8. The extremes of pressure in each group are notable, indicating the wide range within which individuals may vary, yet the average of each group is strikingly constant.

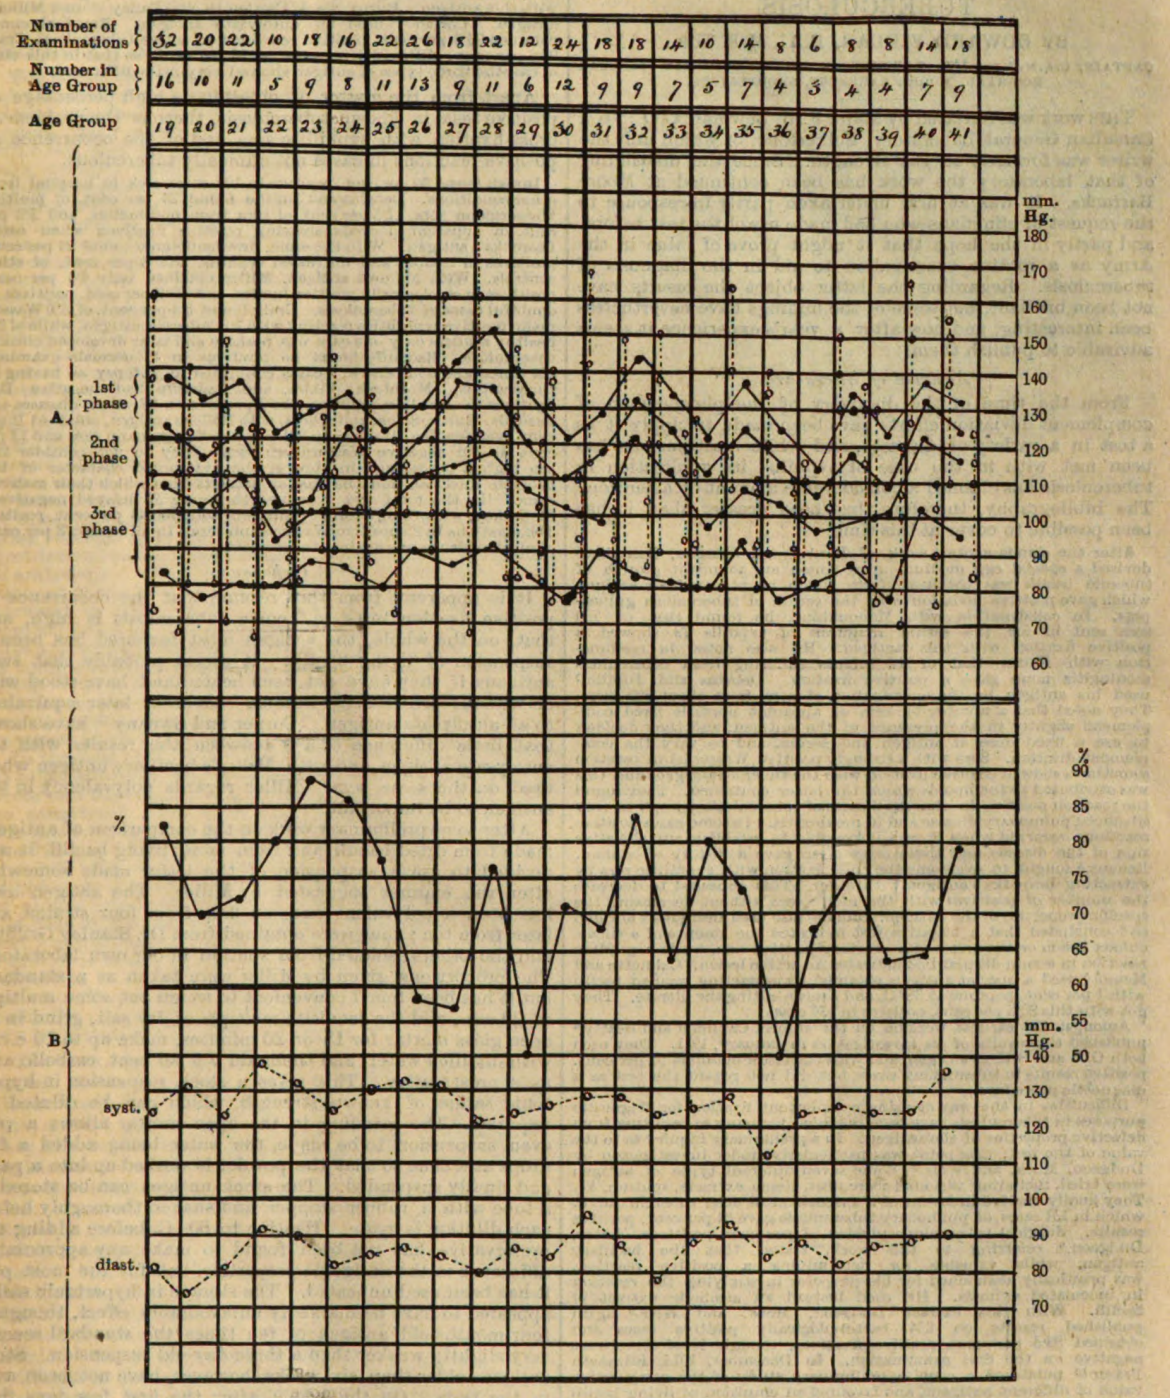
It may be stated here that a careful canvass of the drill instructors and company commanders showed, without exception, that their experience led them to expect more from the men between 21 and 31 than any age before or after. They all equally agreed that the men under 20 and over 35 required much more careful handling.

The conclusions suggested by these considerations are: That the most constant factor, the diastolic pressure, is for all ages somewhere between 70 and 90; that the systolic pressure should be about 50 or 60 per cent. higher than this; that the range of pressure between the two should be capable of differentiation into three different phases—the first, or first tonal, being 20 per cent. of the whole; the second, or murmur, phase 40 per cent.; and the third, or second tonal, 40 per cent. These findings are characteristic of the fit man.

Results in Invalided Men.

Table II. is the analysis of a group of 189 men, all of whom had been invalided home from abroad, but included none of organic heart trouble. Practically all showed, or had showed,

TABLE II.—*Giving a similar Analysis of a Group of 189 Men (not suffering from Organic Heart Trouble) Invalided Home from Abroad.*



evidence of autonomic disturbance of the cardio-vascular mechanism (D.A.H.).

Certain features in the group stand out clearly. The very high percentage of the men who do not show all the phases and the greater instability of the diastolic pressure. That even those who showed all phases show quite a remarkable variation in the relative proportion of these as compared with the first group. It will be noted that the best groups in this table—namely, ages 29 and 36—compare most unfavourably with the worst groups of the first table—namely, ages 37 and 39. These readings were all taken from hospital records, and were made soon after admission and again shortly before disposal.

The conclusions are: (*a*) that the men who are less efficient than normal do not show the characteristic phases which prevail in the group analysed in Table I.; (*b*) that those who are physically fit show these phases in the majority of readings; (*c*) that the result of this simple test is a factor worth considering in estimating the physical capacity of an individual.

The practical application of this test, in addition to its simplicity, takes but little time; two minutes at most.

In selecting and examining the large number of fit men the writer is deeply indebted to Surgeon Lieutenant-Colonel P. H. Whiston, Irish Guards, for many facilities and much encouragement. He was also placed under an equal obligation to Lieutenant-Colonel W. H. Ingilby, Scots Guards, for without his sympathetic coöperation and active help it would have been impossible to carry out the tests.

THE COMPLEMENT-FIXATION TEST IN TUBERCULOSIS.

BY EDWARD FIDLAR, B.A., M.B. TOR.,

CAPTAIN, C.A.M.C.; O.I/C., LABORATORY, NO. XI. CANADIAN GENERAL HOSPITAL, MOORE BARRACKS, SHORNCLIFFE.

THIS work was initiated by Major F. B. Bowman, C.O., No. 1 Canadian General Laboratory, Folkestone, of which unit the writer was formerly on the strength. Since the disbanding of that laboratory the work has been continued at Moore Barracks. It was at first undertaken partly in response to the request of clinicians who had made use of the test before, and partly in the hope that it might prove of value in the Army as a routine examination to aid in the diagnosis of tuberculosis. Regarding the latter object the results have not been brilliant, but some of the findings have nevertheless been interesting, and now after a year's experience it seems advisable to publish them.

Abstract of Literature.

From the time of the discovery of the phenomenon of complement deviation efforts have been made to apply it as a test in a variety of diseases, and while most success has been met with in the case of syphilis, its application in tuberculosis has claimed a considerable amount of attention. The bibliography, therefore, has been greater than it has been possible to cover at this time.

After the fundamental work of Bordet and Gengou, Besredka[1] devised a special egg medium upon which an abundant growth of tubercle bacilli was obtained, from which he prepared an antigen which gave positive deviation with the serum of tuberculous guinea-pigs. In collaboration with Manoukhine, he found that of 750 sera sent in for the serum diagnosis of syphilis 79 showed a positive fixation with this antigen. He also noted in conjunction with Netter that of 12 infants suffering from tuberculous meningitis none gave a positive fixation. Debains and Jupille[2] used his antigen in the examination of sera from about 600 cases. They noted that a number of sera of apparent normals fixed complement slightly in the presence of the antigen, and they decided to use a fixed dose of antigen and serum, and to vary the complement dilution. Sera with a strongly positive Wassermann reaction sometimes showed positive fixation with the tubercle antigen, and this was attributed to the lipoids which the latter contained. They found the reaction positive in almost all cases of tuberculosis except in very advanced pulmonary disease and in meningitis. In some cases positive reactions occurred when it was impossible to establish any objective sign of the disease, and these cases often gave a history of contact. Renaux[3] sought to overcome the cross fixation with syphilitic sera by extracting Besredka's antigen with ether. This appeared to decrease the number of positives with the luetic sera without decreasing the specific properties of the antigen. Inman[4] also used Besredka's antigen and concluded that a negative test indicated the absence of a tuberculous lesion or the arrest of a previously active one, while a positive reaction in serum diluted 1/32 indicated an active lesion. Calmette and Massol[5] used a special antigen obtained by extracting washed bacilli with 1 per cent. peptone at 65° C. and concentrating the filtrate. They got with this 92·5 per cent. positive in 134 cases.

Amongst the earliest workers on the subject Caulfeild and Beatty[6] published the results of an investigation in January, 1911. They used both O.T. and B.E. as antigen, and with the latter obtained 56 per cent. positive results in tuberculous cases, but did not regard the test as a diagnostic procedure.

Difficulties in the way of using complement fixation for diagnostic purposes in tuberculosis have been regarded by many as resulting from defective properties of the antigen. In a preliminary inquiry as to the value of the test, this point was particularly under investigation by Dudgeon, Meek, and Weir.[7] Some seven different types of antigen were tried, including various tuberculins, tissue extracts, sputum, &c. They finally decided in favour of a suspension of dead tubercle bacilli, which in 131 cases of pulmonary tuberculosis gave 84 per cent. positive results. Surgical tuberculosis yielded 57 per cent. positives. Later, Dudgeon,[8] referring to this work, stated that the bacillary antigen, while valuable for determining a positive reaction, was practically abandoned for his purposes in studying the reaction in inoculated animals. He used instead an alcoholic extract of bacilli. With this extract Dudgeon, Meek, and Weir[9] again published results on 234 bacteriologically positive cases and obtained 89·3 per cent. positive fixations, though 15 of these were negative on the first examination. In December, 1913, Elizabeth Fraser[10] published a concise preliminary study of the comparative value of different antigens, and favoured an emulsion of living bacilli from glycerine potato. She found 68 per cent. positive reactions in tuberculous sera. Again, McIntosh, Fildes, and Radcliffe,[11] used moist living bacilli in saline and in 43 pathologically certain cases of phthisis obtained 76·7 per cent. positive fixations, and in 26 surgical tuberculous conditions, excluding adenitis, obtained 80·7 per cent. positive. In another article on the subject Radcliffe,[12] who refers to the earlier work of Bordet and Gengou, Wassermann and Brück, Citron, Lüdke, Morgenroth and Rabinowitsch, Hammer, Bang and Anderson, and others, was led by his own work to favour also a fresh suspension of bacilli as antigen. His results showed about 90 per cent. of 568 cases of pulmonary tuberculosis to give a positive reaction.

The more recent work in the United States has shown some very favourable results. Bronfenbrenner[13] made a study of Besredka's antigen and concluded that the lipins should all be extracted, and though a certain number of clinically non-tuberculous cases react positively the reaction nevertheless appeared to be specific. Craig[14] and McCaskey[15] used an alcoholic extract of several strains of T.B. grown upon Vedder's starch medium. Miller[16] and Zinsser prepared their antigen by grinding 20 mg. of moist T.B. mass with 90 mg. of dry salt in a sterile tube, and then adding 10 c.cm. of distilled water to make an isotonic suspension. Heating to 60° C. for half an hour appeared to have no deteriorating effect. Miller[17] published very good results with this antigen. Burns, Slack, Castleman, and Bailey[18] used Miller's antigen. Corper[19] used an autolysate antigen. Bronfenbrenner obtained 98·3 per cent. positive reactions in active tuberculosis, Craig 96·6 per cent., Miller 96·8 per cent. to 93 per cent., so that in this class of case the three types of antigen showed very little difference.

Apart from the matter of obtaining a high percentage of positive tests in known tuberculosis, there is the problem of cross-fixation with syphilitic sera and of the occurrence of positive reactions in cases not clinically tuberculous.

Inman found 24 per cent. positive in 100 cases sick in hospital from other conditions. Debains and Jupille found 24 per cent. of positive Wassermann sera, 17·3 per cent. of sera from non-luetics, and 3·2 per cent. of apparent normals showing positive fixations when using Besredka's antigen. With the same, Bronfenbrenner found 24 per cent. positives in treated and untreated syphilis, and 8 per cent. of other controls. With his own antigen, Miller obtained only 4·4 per cent. positives in serologically positive luetics, and 22·8 per cent. positives in doubtful cases of tuberculosis. Craig found 5·4 per cent. of 350 Wassermann positive syphilitics reacting with his tubercle antigen, while of 200 healthy soldiers only one case was positive and later developed clinical tuberculosis. Radcliffe found no positives in 45 normals examined 204 times, and none also in 9 cases confirmed at autopsy as having no tuberculosis. McIntosh, Fildes, and Radcliffe had negative Tbc. fixations in all of 18 syphilitics, and 3 positive in 87 other diseases and normals. Burns, Slack, and others, with Miller's antigen, obtained 15 per cent. positive Tbc. fixations in 221 positive Wassermann sera and 13 per cent. in 691 negative Wassermann sera. They do not consider this too high a percentage in view of the widespread character of the tubercle infection and the class of patients from which their material came. (In the total sera examined they note 37 delayed negatives.) McCaskey, with Craig's form of antigen, obtained 44 per cent. positive Tbc. fixations in 25 positive Wassermann sera. In all except 8 per cent. clinical evidence was against tuberculosis.

Technique.

It is apparent from this résumé that the occurrence of positive fixation tests in known tuberculosis is high, and that, on the whole, the antigen most favoured has been a suspension of living bacilli. It seems probable that such antigens if they have not been heated and have stood with or without preservative become sooner or later equivalent to an autolysate antigen. Corper and Sweany[20] have shown that little difference occurs between the results with the autolysate antigen and with Miller's bacillary antigen when used on the same sera. Miller regards polyvalency in the antigen to be important.

After some preliminary work on the comparison of antigens made from dried bacilli and from moist living bacilli, it was decided to use a suspension of the latter made somewhat after the manner suggested by Miller. The antigen used has been a polyvalent one—at first from four strains, and later from ten; four were obtained from Dr. Stanley Griffiths and the others isolated from sputum in our own laboratory. The proportions given by Miller were taken as a standard, but it has been found convenient to weigh out some multiple of 20 mg., add the requisite multiple of dry salt, grind in an open glass mortar for 15 or 20 minutes, make up to 10 c.cm. with distilled water, and then add 0·5 per cent. carbolic acid as a preservative. This gives a stock suspension in hypertonic saline of known strength which can be diluted as required. The grinding in the open mortar allows a very even suspension to be made, the water being added a few drops at a time so that the powder is worked up into a paste and finally suspended. The stock antigen can be stored in a tube with a rubber stopper and shaken thoroughly before each dilution is made. Heating to 60° C. before adding the preservative has not been found to make any appreciable difference in the antigenic properties, but for the most part it has been used unheated. The storage in hypertonic saline appeared to have no markedly unfavourable effect, though a four-months-old antigen of ten times the standard seemed very slightly weaker than a three-day-old suspension. Stock antigens older than six weeks, however, have not been used in the tests. On the whole, after the first few days they have been found to remain comparatively uniform for more than six weeks. The anti-sheep-cell system has been used throughout with amboceptor supplied from Burroughs, Wellcome, and Co. Complement has been obtained, as a rule, from three or more guinea-pigs. This point seems to be of some importance, for differences in action towards the same antigen have been found in comparative titrations of the sera of individual animals. Radcliffe also noted differences in his work.

The patient's serum has been inactivated at 55° C. for 15 minutes in some cases, in others for 30 minutes. This point did not seem to be of great importance, and most of the sera had the longer inactivation. It is important, however, that the sera be fresh, for there seems to be a

distinct tendency for some sera, stored several days in the ice-chest, to develop substances of such quality and quantity as to produce a positive reaction without being detected as anticomplementary bodies in the serum control. Such reactions are undoubtedly false.

The actual test made at first was similar to that described by Kolmer[21] for the Wassermann reaction as Method I., except that one-quarter the amounts of the hæmolytic system were used. The patient's serum was tested in 0·05 c.cm. and 0·1 c.cm. amounts, with a serum control of each quantity, making a four-tube test in all. An antigen dilution containing the quantities given by Miller was used, its anticomplementary value obtained, and at most one-third of this used in the test. Titration of the amboceptor was always made for each day's tests in the usual manner and the cells employed were sensitised with two units of amboceptor. In the following paragraphs this method will be referred to as Method I.

Later, and for the greater part of the work, another method was employed, similar to that described as Method IV. for the Wassermann test recommended in the report of the Special Committee upon the Standardisation of Pathological Methods of the Medical Research Committee. Three slight modifications were introduced; first, the use of 2 m.h.d. of complement in the serum control instead of 3 m.h.d. as being more accurate for detecting anticomplementary substances; second, the use of 0·1 c.cm. of patient's serum in the place of 0·25 c.cm. of a 1 in 5 dilution—i.e., just twice the quantity of actual serum; third, the use of a 2·5 per cent. suspension of sheep cells instead of 3 per cent. In this method, hereafter referred to as Method IV., the m.h.d. of complement is first determined by titration with cells sensitised with 5 m.h.d. of amboceptor. 0·1 c.cm. of serum to be tested is placed in each of three tubes; in the first is placed 3 m.h.d. of complement, in the second, 5 m.h.d., and in the third (serum control) 2 m.h.d. The dose of antigen which is placed in the first and second tubes binds by itself not more than 1 m.h.d. of complement as determined by titration before each day's tests. The 5 m.h.d. cells are used throughout. The total volume in each tube is 1 c.cm. Both in the titrations and in the actual tests incubation takes place for 1/2 hour at room temperature and 1/2 hour at 37°C. before the addition of cells.

In the case of Method I. readings were taken at the end of 15 minutes and 30 minutes of the final incubation, as some observers have stated that small amounts of fixation must be considered. The 30 minutes was concluded to be best. Provided the controls were clear, complete inhibition in both the 0·05 and 0·1 tubes was called +++; partial inhibition in the 0·05 tube and complete in the 0·1 tube was called ++; slight or no inhibition with 0·05 c.cm. of serum, but complete or almost complete with 0·1 c.cm. of serum, was called +. In the case of Method IV. complete inhibition in both 3.m.h.d. and 5 m.h.d. tubes is called +++; complete inhibition in the 3 m.h.d. tube and partial in the 5 m.h.d. tube ++; complete inhibition in the 3 m.h.d. with slight or none in the 5 m.h.d. tube +. The serum control must of course show complete hæmolysis. Lesser degrees of inhibition in the 3 m.h.d. tube can be indicated by ± and ±.

The work began with the testing by Method I. of sera from known cases of tuberculosis and of sera sent in for the Wassermann test. In over a consecutive 100 of the latter this method yielded 21·6 per cent. positives. While I was only able to obtain further history in about one-third of the positive cases, none of these gave definite clinical evidence of active tuberculosis. This percentage was rather higher than expected at that time, and it was concluded that Method I. was perhaps too sensitive, although in sera from active tuberculosis it gave only about 80 per cent. positive results. Method IV., in comparison, showed in the same routine sera only 6·8 per cent., with a trace or more of Tbc. fixation, so that this fact rather favoured the choice of this method for further work. Certain other features recommended the adoption of Method IV. First, it was preferred as being more nearly a quantitative test, since the number of plus signs used in the readings corresponded rather closely to the number of units of complement specifically fixed. Secondly, the use of cells sensitised with five units of amboceptor appeared to be the most practical way to overcome the difficulty arising from natural sheep amboceptor in human serum, for at this high dosage the reciprocal relations between complement and amboceptor are unaffected. This has been indicated in the work of Kaup and Kretschmer.[22] Thirdly, this method for making the fixation tests for tuberculosis was more convenient owing to the adoption about this time of a similar method of performing the Wassermann test, because the same complement titration was applicable to both. In the fourth place, if it were found necessary, it would be a very simple matter to increase the sensitiveness of the test by reducing the amount of complement allowed for specific fixation.

As bearing on this last point it is surprising how much complement can sometimes be bound by tuberculous sera in the presence of the tubercle suspension. On one occasion, in 2 out of 6 strongly positive sera (0·1 c.cm. amounts), over 10 m.h.d. of complement were fixed. True, these are exceptional, but they are a good indication of the specificity of the reaction, and suggested at the time that to allow for the specific binding of 1 m.h.d. of complement (i.e., 1 unit over and above the total amount which is absorbed by the serum and antigen alone) would make the test sufficiently sensitive for practical purposes. Method IV. therefore was adopted for the greater part of the work.

Results.

The results here recorded are based on a total of 570 different cases. A great many more tests than this have of course been carried out, for sera have been repeated and comparisons made between the two methods of performing the test. Comparisons have also been made between antigens, between different quantities of the same antigen, between different quantities of the same serum, to determine the suitable amount for testing, and so forth, the outcome of which has been the employment of Method IV.

The accompanying table presents the more important part of the results in brief form.

Table of Results.

Description of cases.	Method used.	No. of cases.	Classification of cases.	Readings.				
				Neg	±	+	++	+++

199 cases tuberculosis, all kinds, showed 16 positive Wass. tests.

Discussion and Conclusions.

1. *The diagnostic value of the test.*—The percentage of positive reactions in active pulmonary tuberculosis—77 per cent. (Method I.), 74 per cent. (Method IV.)—is not as high as that published by the American workers, but approximates the earlier results of Dudgeon, Meek, and Weir, and of McIntosh, Fildes, and Radcliffe. If the ± reactions of

Method IV. are included the percentage by this method rises to 80. Certainly this method could be made much more sensitive and to give a higher proportion of positives, but from the figures in the cases not clinically tuberculous it appears probable that the test would then be robbed of its practicality. In fact, even with these present results the practical value is in considerable doubt. Captain G. S. Gordon, O.i/c G.U. surgery at this hospital, to whom I am indebted for the histories in the majority of the cases not clinically tuberculous, found the test of no definite assistance, chiefly because in genito-urinary disease if the Tbc. fixation be positive it does not localise the lesion in the genito-urinary tract, and usually in active tuberculosis the disease can be diagnosed by other methods. On the other hand, it has been reported by Captain Farquharson, O, i/c Laboratory, 15 C.G.H., that the test has in some cases been an aid to the clinician in reaching a diagnosis.

The best results published have been those of Miller and of Craig. They obtained the highest percentage of positives in the known tuberculous (about 98 per cent.), with the lowest percentage in the non-tuberculous (between 4 and 5 per cent.), although each used a different antigen. From the experience of others one cannot help thinking that these two observers have been particularly fortunate in the class of their cases. McCaskey, with Craig's antigen, and Burns, Slack, and others, with Miller's antigen, have not had such striking results. In this present work the effort has been, not to make the test more sensitive, but, if anything, less so, in order that a strong reaction may be a reliable fact with a definite significance to the clinician. It is disappointing when a case is clinically tuberculous and gives a negative test; but if one tries to push it to the 100 per cent. limit, then the test seems to lose the slight value it may have in the doubtful cases. Method IV. is conservative, and in spite of two or three cases met with, it would appear that the +++ reaction can be relied upon under the proper conditions as a definite aid in diagnosis, but the number of cases in which it will clinch a diagnosis that could not be made by other methods will be few. In view of this and the widespread character of the infection, therefore, one is led to agree with McIntosh, Fildes, and Radcliffe, that "however perfected, it can never attain to the great practical value of the Wassermann reaction."

2. *The significance of a strong reaction.*—The strong reactions, +++ of Method IV., occurred most frequently, as would be expected, in active tuberculosis, 35 per cent. in incipients, 37 per cent. in the moderately advanced, 48 per cent. in the advanced. The last figures are higher than one would be led to expect from the work of some, but differences may depend upon whether the cases were gaining, holding, or losing, a classification which was not made in this list. This +++ reading indicates that 0·1 c.cm. of the patient's serum binds specifically three or more free units of complement. The large amount which can sometimes be fixed has already been noted. Comparisons cannot be made with others on this point, except that fixation was obtained by Inman in some sera diluted up to 1/256, and by Dudgeon, Meek, and Weir up to 1/1000 in a few cases. Meek[23] adopted as a standard of a strong reaction fixation in a serum diluted 1/10. On this basis he found the highest proportion of strong reactions (65 in 102 = 63·7 per cent.) in cases with the physical signs of extensive pulmonary disease—copious sputum, impaired general health, and apparently bad prognosis. Caulfeild[24] also made the observation that the patients whose sera maintain the complement-fixation result seem to go rapidly backwards. This reading therefore would seem to have some value in prognosis, though it also seems to be generally accepted that very far advanced cases are very often negative. Meyer,[25] in noting this, divides the third stage cases into late and early. The diagnostic value of the +++ reaction has been referred to. If it should occur in a clinically doubtful case it would appear to be fairly reliable, for it has been noted in only 1·8 per cent. of the clinically non-tuberculous.

3. *The significance of a negative reaction.*—This result means more to those who use a more sensitive method of testing, perhaps; but in this present work it appeared to be of no importance except in the very advanced stages. While the positive reaction occurs most frequently in active disease, it does not serve as an absolute indication of it, a view in agreement with the conclusions of Corper and Sweany. Neither is a negative reaction a certain sign of absence of activity. In this test we may be dealing with a peculiarity of the individual rather than a type of case. If the serological reaction of every patient to the same quantity of tubercle toxin were equal, then the amount of complement deviation would be a precise measure of the balance between the walling-off process and the absorption of toxin. This supposition is untenable in a mathematical sense, and seems unlikely even in a general way, judging from animal experiments. The irregularity of serological response to humanisation of individual animals is well known, and Dudgeon makes a note of it, in particular with rabbits inoculated with tubercle bacilli under exactly similar conditions. The interesting idea expressed by Miller concerning arrested, sputum-positive cases, with a negative fixation test, that they are really not suffering from the tuberculous condition, but are simple carriers, may be giving too much significance to a negative reaction.

4. *The significance of the test in the clinically non-tuberculous.*—Of the 215 cases coming under this class, the fixation test was positive in 21·8 per cent., or in 28·3 per cent. if the ± result be included. These figures are not unworthy of comment. They appear high as compared with those published by others from civilian patients. They may be taken to suggest that the wear and tear of war has reawakened dormant lesions sufficiently to produce antibody without sign or symptom, or that the more intimate contact of the soldier's life has seeded down more individuals than in peace times. This question must be left to others to discuss, but as bearing out the suggestion the following may be noted. In the Medical Supplement for August 1st, 1918, a reference is made to several writers having stated that tuberculosis has increased in the German Army considerably during the war. Ronzoni[26] is quoted as stating that 75 per cent. of soldiers (Italian) are infected with tuberculosis, judging by the cutaneous reaction, and that 20 per cent. have clinically active lesions. Brugnatelli[27] found tuberculous changes in 72 out of 304 autopsies (23·6 per cent.). Judging from the latter figures, therefore, the results in our 215 soldiers are not so much out of the way. That contact is of importance in the fixation test is noted in the special group of 96 cases, and family history, without definite contact being established, seems to have no significance. The percentage of those with history of contact which show positive reactions is as high as 75 if the ± readings are included.

5. *Non-specific fixation.*—Most of those who have worked with the test recognise that the reaction is definitely specific in the majority of cases, but that the probability of cross fixation exists in strongly positive syphilitic sera. This probability is also indicated in the results here published, even though a bacillary suspension was used as antigen. Of the 23 sera showing a positive Wassermann and tested by Method I., 43·5 per cent. showed Tbc. fixation, which is practically the same as the findings of McCaskey, who used Craig's antigen. Method IV., however, appears to reduce the percentage, as only 21·8 per cent. showed a trace or more of Tbc. fixation in the 32 syphilitic sera tested by this method. One interesting case seemed to have a direct bearing on the subject. The man had a bronchitis and was a Tbc. suspect with syphilis; at the first examination both the Wassermann and the Tbc. fixation tests were +++. His serum was sent in again several weeks later after finishing his course of antisyphilitic treatment because of a persistence of some suspicious features and his bronchitis. The reactions on this occasion were both negative, and later, on clinical grounds, he was concluded to be non-tuberculous. A Wassermann test has been made on every case here reported, and it still seems advisable that no interpretation of a Tbc. fixation test should be made without knowing this other test as well. There has been a suggestion of some non-specific fixation in cases of nephritis, but the number has been too small to warrant a definite statement.

6. *Positive Wassermann reactions in the tuberculous.*—Incidentally it has been shown that 8 per cent. of cases of tuberculosis have a positive Wassermann reaction. Von Adelung,[28] in California, found 8·7 per cent. of 195 bacteriologically proven cases of Tbc. to give this, while in Illinois, Corper and Sweany found it in 7·1 per cent. of 1290 sanatorium patients. Taken as an indication of syphilis, it seems worth noting, therefore, that the proportion amongst our tuberculous soldiers is practically not greater than occurs in the civilian population.

Acknowledgments.

As has been mentioned, this work was begun at No. 1 Canadian General Laboratory, then under the command of Major F. B. Bowman, in collaboration with whom some of the preliminary experiments were made. It was continued under the régime of Captain F. Adams at the same place, and later carried on at Moore Barracks after the disbandment of the laboratory in Folkestone.

I am especially indebted to Major F. H. Pratten, of the Canadian Special Hospital, Lenham, for sympathetic assistance in the arrangements for collecting material, and in the classification of the tuberculous cases. My thanks are also due to Captain H. R. McIntyre and Captain A. McKay, of this hospital and to Captain C. D. Farquharson and Captain D. H. Paterson, of No. 15 Canadian General Hospital, and to Captain G. H. J. Pearson, of the Canadian Special Hospital, Etching Hill, who all furnished me with histories of cases. I have already mentioned my indebtedness to Captain G. S. Gordon for many histories.

The privilege afforded by the Royal Society of Medicine to make use of their library has been greatly appreciated.

I desire to record the faithful work carried on by Sergeant E. D. Brown, Corporal F. E. Townsend, and Corporal M. J. Coomer during the whole course of this study, both at No. 1 Canadian General Laboratory, and afterwards at Moore Barracks.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ACUTE POLIOMYELITIS IN AN INFANT 12 DAYS OLD, WITH EXTENSIVE PARALYSES AND RECOVERY.

BY T. H. GUNEWARDENE, M.R.C.S., L.R.C.P. LOND.,
RESIDENT MEDICAL OFFICER, EAST LONDON HOSPITAL FOR CHILDREN.

THERE seems to be no case on record of acute poliomyelitis (infantile paralysis) with characteristic signs and symptoms in so young an infant. Cases of intra-uterine poliomyelitis have been spoken of, but without pathological and only little clinical evidence. There is every possibility that some deaths of the new-born with convulsions may be due to the virus of acute poliomyelitis, but the proof is yet to come. In the Monograph of the Rockefeller Institute for Medical Research (June 24th, 1912) reference is made by Peabody, Draper, and Dochez to a case two weeks old as the youngest recorded in the New York epidemics up to the time. The notes given below describe a typical text-book case as to mode of onset, pathological findings (except for the leucopenia), and after-results.

Notes of the Case.

The patient (Edward C——) was born on Sept. 1st at full term; normal labour of three hours' duration; no cyanosis at birth. He was the eleventh child; three miscarriages in early part of married life; one child died when 14 days old; other children and parents healthy.

The infant was admitted on Sept. 18th with complaint that the mother on the 13th, while washing him, noticed all limbs "limp"; he had not been crying since the 14th; last quite well on the 12th. No gastro-intestinal complaint; "takes very well"; fed on Nestlé's milk.

On admission baby was well nourished. There was slight cyanosis; breathing shallow. The neck and muscles of trunk were quite flaccid; facial muscles unaffected; no strabismus. Attempts at crying were unsuccessful. All limbs were quite flaccid except for voluntary movements of right hand and fingers; abdominal muscles and intercostals paralysed, *diaphragm alone working.* Knee-jerks not obtained. Sensations apparently not affected.

Five days after admission movements of the right forearm, left hand, and fingers were noticed; on the sixth day successful but feeble cry and movements of the left toes. Steady and gradual recovery of movements of the extremities and neck continued, the only permanent paralyses left at the end of ten weeks being those of the anterior group of muscles of the right leg, those of the left upper arm (except the biceps), and intercostals and abdominal muscles with their respective deformities of right foot-drop, flexion of left elbow, and an elongated, funnel-shaped chest with wasted muscles, and a flaccid protuberant abdomen. Electrical reactions were not made. No rise of temperature was recorded all the time. Patient was discharged on Dec. 5th.

Pathological findings.—I am much indebted to Dr. E. A. Ross for these investigations:—

Sept. 19th: Lumbar puncture fluid, 100 cells per c.mm., 91 per cent lymphocytes, 9 per cent. polymorphs, sugar present, globulin increased, cultures sterile.
Sept. 19th: White cell count, 4600 per c.mm.
Sept. 24th. White cell count, 5000 per c.mm.
Sept. 27th: Lumbar puncture fluid, 40 cells per c.mm., 99 per cent lymphocytes, 1 per cent. polymorphs, sugar present, globulin increased, cultures sterile.
Oct. 9th: Wassermann reaction on the mother, negative result.
No tubercle bacilli were found in the cerebro-spinal fluid.

As to treatment, urotropine in 2-gr. doses by the mouth and small doses of atropine and strychnine subcutaneously were given during the earlier weeks.

This case was kindly seen by Dr. Farquhar Buzzard in consultation, who agreed with our diagnosis. I must thank Dr. Clive Riviere, under whom the patient was admitted, for allowing me to publish the case.

PRIMARY NOCARDIASIS OF THE LACRYMAL GLAND.

BY J. B. CHRISTOPHERSON, M.A., M.D. CANTAB., F.R.C.P. LOND., F.R.C.S. ENG.,
DIRECTOR OF THE CIVIL HOSPITALS, KHARTOUM AND OMDURMAN;
AND
R. G. ARCHIBALD, M.B., CH.B. EDIN.,
MAJOR, ROYAL ARMY MEDICAL CORPS.

THE following is a note of a case of primary nocardiasis of the lacrymal gland, caused by a species of nocardia hitherto undescribed. The lacrymal gland appears to be one of the most remarkable glands in the body. Having few disorders of its own, it fulfils its destiny undisturbed by the disorders of the outside world, content to be left alone to administer its secretion to the great master-tissue the eye. The disease here recorded represents nocardiasis or actinomycosis, in which the causal agent is a germ or fungus, which grows readily aerobically and produces arthrospores.

The patient, a male aged 22, was admitted to hospital suffering from a swelling of the right eye, and inability to open it. The duration of the case was three and a half years. There was neither scar nor wound visible. The eyelids could not be everted, but when raised a thick yellow discharge poured out, and the whole conjunctival surface of the upper lid appeared to be rough and granular, with deeper ulceration in parts. The swelling was painless, and was of doughy consistency, though without œdema. There was a bulging forwards of the fornix of the conjunctiva. No lymphatic glands were enlarged, and the sight was unaffected. The eyeball itself was not invaded, nor were its movements involved, neither was photophobia or lacrymation present.

Under chloroform, the growth was dissected away; it appeared to have commenced in the lacrymal gland, and to have spread into the upper lid, invading the tarsal cartilage. It extended also somewhat between the eyeball and the bony orbit, along the ducts of the lacrymal gland.

Sections showed the morbid histology commonly associated with a fungal infection. A portion of a grain flattened between a slide and cover-glass showed that it was composed of the typical nocardial bacilliform hyphæ, with rounded bodies or spores, the whole being held together in a dense matrix. The reactions in various culture-media were investigated. The animal experimentation has not been concluded, but the condition does not seem to be pathogenic to the grey monkey.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

A MEETING of this section was held on Dec. 5th, Mr. J. D. MALCOLM, the President, being in the chair.

Foreign Body in the Gravid Uterus.

Dr. G. DRUMMOND ROBINSON showed a Skiagram of a Foreign Body in the Gravid Uterus. The patient, an unmarried woman, was admitted to hospital with a history that, thinking she was pregnant, she had tried to pass a crochet needle, the hook end of which was covered by a metal cap, into her uterus per vaginam. On withdrawing the crochet needle she was alarmed to find that the cap had not come away with it. She had hæmorrhage from the vagina, and on becoming frightened came to the hospital. The uterus was found to be bulky and the os was slightly patulous; no part of the metal needle-cap could be felt. The metal cap was clearly seen in several X ray photographs. Shortly after the skiagrams were taken the patient passed an ovum of about two months, together with the metal cap, spontaneously during an action of the bowels. The metal cap measured 2 1/10 in. in length.

A Uterus in which Changes had taken place as the Result of Procidentia.

Dr. DRUMMOND ROBINSON also read a paper on the above subject. The patient, aged 46, had complete procidentia of the uterus in 1900 (18 years ago) after the birth of her second child. In 1901 (17 years ago) hysteropexy was performed. In 1902 (16 years ago) the patient was confined of her third child. Shortly after this confinement the prolapse reappeared. In 1903 (15 years ago) Dr. Robinson first saw her. The vagina was completely prolapsed; the sound passed 8 inches; the supravaginal portion of the cervix could be felt through the vaginal walls, much elongated and very thin; the fundus uteri appeared to be attached to the anterior abdominal wall. An extensive perineal operation was performed, which enabled the patient to retain a pessary. Within a year the uterine canal had become so shortened that the sound only passed 3½ inches. There had been no further pregnancy. Lately the patient had had hæmorrhage from the vagina, and a year ago Dr. Robinson removed the uterus by Wertheim's method for carcinoma of the cervix. The fundus uteri was found firmly attached to the anterior abdominal wall. Immediately after the operation the sound passed through the external os 4½ inches into the uterus. The body of the uterus appeared to be enlarged. The patient made an uneventful recovery. The specimen was shown. Whatever the nature of the elongation of the supravaginal cervix in cases of procidentia might be (whether stretching of that structure alone, or new growth of its tissues, or both), this case proved that it might disappear to the extent of 4½ inches after the uterus had been replaced, even when the procidentia had lasted for as long as three years. He thought that such elongations might be, and probably at first always were, entirely due to mechanical stretching of the cervical tissues. Ventrofixation without support of the vagina by some means from below was insufficient for the relief of a really bad case of prolapse.

Dr. A. LAPTHORN SMITH said that at first he used to leave about 2½ inches of cervix, but found there was always some involution. He now left 3½ inches and found that the cervix later became 2½ inches.

Dr. HERBERT WILLIAMSON said that elongation of the supravaginal cervix might frequently be due to stretching, but in later stages structural changes might produce permanent elongation.

Dr. AMAND ROUTH agreed that stretching might occur at first, but if the cervix was allowed to remain down it became thickened and permanently elongated.

Dr. W. S. A. GRIFFITH asked what held up the body of the uterus and yet allowed the cervix to stretch like this.

Lady BARRETT gave an account of a case of a much elongated cervix, certainly due to stretching.

Labour in a Paraplegic Woman.

Dr. DRUMMOND ROBINSON gave an account of a case of labour in a paraplegic woman. The patient, aged 31 years, who had had seven children, was admitted to hospital in August, 1909, suffering from paraplegia of recent origin, probably due to transverse myelitis in the dorsal region of the cord. In October she was found to be three months pregnant and was transferred to the obstetric ward. During the time which preceded her confinement she suffered from bedsores, many rises of temperature, two attacks of congestion of the lungs, and offensive urine. The gravid uterus increased in size abnormally slowly after the fifth month and at full term was only as large as an ordinary seven months uterus. Labour took place 281 days from the cessation of the last menstrual period, and was painless, but otherwise entirely normal. Involution and lactation were normal. In 1897 Dr. Amand Routh read a paper before the Obstetrical Society of London in which he gave notes of seven similar cases, together with notes of a case of his own. Since then there had been no other similar case recorded. The fact that parturition and lactation occurred normally in these cases and in animals in which the lumbar part of the spinal cord had been removed suggested that these fnnctions were carried on without the aid of the higher nerve centres, and the physiological stimulus to both these functions appeared to be the result of some chemical substance or substances, probably produced in some part of the reproductive system and conveyed direct to the uterine muscle and mammary gland by the blood stream. The most recent experimental research confirmed this view.

Dr. AMAND ROUTH said that in his case post-mortem examination showed that there was no communication in the spinal cord above the third and below the sixth dorsal vertebræ. At the confinement there was no proper intermission between the pains, which suggested that some control was missing. He thought that the explanation was that onset of labour was almost certainly due to biochemical action, the chemical substance starting the process probably being derived from the junction of the maternal and fœtal circulations, and acting on the lumbar plexus rather than directly on the uterus. Experiments showed that if the lumbar plexus were separated from the pregnant uterus the uterus was left very inert, whereas stimulation of the lumbar enlargement caused the uterus to expel its contents very violently. At the time of his observations lactation was supposed to be the result of nervous influence due to the uterus being empty, but in this case it must have been due to a chemical substance.

Dr. LAPTHORN SMITH drew attention to the fact that painless labour had occurred under spinal anæsthesia.

Dr. DRUMMOND ROBINSON said that he had performed Cæsarean section on a patient under spinal anæsthesia. The operation was perfectly painless and the uterus acted strongly. Experiments had been carried out by Professor Starling and Dr. Janet Lane-Claypon on virgin rabbits, changes such as occur in nature as the result of pregnancy being produced as the result of injection with various parts of a fœtus. It was thus evident that there was something in the fœtus which was capable of stimulating the mammary gland.

Puerperal Anuria.

Mr. CLIFFORD WHITE showed microscopic sections and small portions of kidney removed during nephrotomy on two patients suffering from puerperal anuria. In both the partial suppression of urine had lasted about ten days, and in both cases immediate recovery followed incision of the fibrous capsule of the kidney. The chief change shown microscopically was marked dilatation of the tubules. Thrombosis of the vessels was absent. It was suggested that in cases of puerperal suppression of urine inflammatory swelling producing increased tension within the fibrous capsule of the kidney caused pressure on the collecting tubules and so prevented the urine from reaching the ureter. This hypothesis was supported by the fact that (*a*) in some eclamptic patients passing little water the kidney is hard on direct palpation during Cæsarean section; (*b*) the dilatation of the tubules was present in portions of the kidney removed during operation while the suppression still continued; and (*c*) casts were present immediately after incision of the capsule although they had been absent previously.

Dr. LAPTHORN SMITH said that there were, no doubt, cases like this where suppression was due to pressure on the tubules. In eclampsia, he thought, the suppression was due to pressure on the large veins, and as soon as this was removed the blood could circulate.

Dr. J. S. FAIRBAIRN said that many cases of suppression had no eclampsia at all, and often no symptoms except coma. He disagreed with the previous speaker. In eclampsia it was

a toxin which caused the damage, and opening the capsule would do little good.

Dr. H. RUSSELL ANDREWS said that anuria was only part of eclampsia; the most remarkable part was the profound toxæmia.

MEDICAL SOCIETY OF LONDON.

Epidemic Encephalitis.

A MEETING of this society was held on Dec. 9th, Dr. A. F. VOELCKER, the President, being in the chair, when Dr. E. FARQUHAR BUZZARD read a paper on Lethargic Encephalitis, which appears in full on page 835 of our present issue.

Discussion.

In the course of the discussion Mr. PERCY SARGENT spoke of the appearance of the brain, &c., during life, as seen at the time of operation. The dura mater was friable or thickened, and there was blood on the surface; the cortex was friable. Operation had been of no use in either of these cases, but might prolong life. A better method might be repeated lumbar puncture.

Dr. F. G. CROOKSHANK, speaking from the epidemiological point of view, said they had no right to distinguish between epidemic prevalences and to say that they were due to a different disease because of difference in seasonal and in age incidence.

Dr. J. G. GREENFIELD agreed that this was not a new disease. There was negative evidence from the clinical, bacteriological, pathological and epidemiological points of view that it was not the same disease as poliomyelitis. Positive evidence showed that poliomyelitis was a lymphogenous infection—was carried by the lymph stream—whereas this was a hæmatogenous infection, the blood-vessels bearing the brunt of the disease.

Dr. EDMUND CAUTLEY also spoke.

Dr. BUZZARD, in reply, agreed that if one could recognise these cases for certain one would not decompress. With regard to Dr. Crookshank's contention, he said that encephalitis was a prevalent disease. From the clinical standpoint there was a form of encephalitis like poliomyelitis and due to the same virus. From the pathological side he had examined numerous cases of encephalitis of the poliomyelitis type, and in these it was difficult to say where the infection began or ended; the whole nervous system was affected. In lethargic encephalitis, on the contrary, the condition was patchy. Poliomyelitis was an inflammation of the nervous matter; lethargic encephalitis was an inflammation of blood-vessels with *consequent* effect on nervous tissues.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Military Surgery of the Lung.

A MEETING of this society was held under the chairmanship of Sir JOHN W. MOORE.

Colonel WILLIAM TAYLOR read a paper in which he briefly reviewed the surgery of the lung as carried out at the "front." He showed that the change was simply that of harmonising or adapting the principles of surgery as they are now applied to other wounds to those of the lung and chest. It was estimated that the mortality due to chest wounds at the regimental aid posts varied from 25 to 30 per cent. At the casualty clearing stations the mortality averaged about 18 to 20 per cent., while at the base hospitals it was about 10 to 12 per cent. The average general mortality of chest wounds was about 18 to 20 per cent.—a state of things unsuspected at the beginning of the war. This high mortality, Colonel Taylor said, is due to the fact that shell wounds preponderate over bullet wounds to the extent of 3 to 1. The mortality of shell wounds as compared with bullet wounds is as 14 to 1. It is the septic dangers in connexion with shell wounds that render them so dangerous. The mortality is highest during the first 48 hours, during which time it is calculated that 60 per cent. of the deaths occur. Open wounds of the chest are grave as compared with closed wounds. They are at least twice as dangerous. Lung wounds are like other wounds. They are contaminated by the mere entrance of the foreign body, whether it is retained or not. Like any other wound, there is an area of necrotic tissue which forms a culture medium for the growth of organisms. As with any other wound, in a few hours it will become infected, and the infection will follow the same course. Twenty-five per cent. of wounds of the lung are fatal from hæmorrhage and asphyxia. Surgeons now endeavour to arrest the bleeding by direct surgical intervention at many casualty clearing stations. It has been shown that the operation of thoracotomy has little or no effect upon external blood pressure. Operations can be performed successfully upon the chest and lung in patients with a blood pressure as low as 50 mm. Hg, a point of great practical importance. The gravity of the prognosis of lung wounds is increased considerably by the frequency with which pleuro-pulmonary lesions of the opposite side occur. Infection of the hæmothorax in bullet wounds is exceptional. When there is an opening in the thoracic wall an aerobic infection from without is added to the anaerobic infection arising from the pleuro-pulmonary wound. It is partly on account of this wound infection that open wounds of the thorax are so dangerous. The gravity of chest wounds from the fifth day onwards is due to pleural suppuration much more than to infection of the lung itself. The treatment of penetrating wounds of the lung depends upon whether the wound is superficial, whether the foreign body is retained, or whether the case is one of the through-and-through type. The foreign body is removed where possible together with fragments of bone and pieces of clothing. The track is cleansed and the opening into the lung is carefully closed. This closure tends to arrest hæmorrhage, and will diminish the likelihood of infection of the pleura from the lung. Primary extraction of all foreign bodies from the lung must be considered the rational treatment for preventing infection. Access can be gained to the lung most satisfactorily by an incision from the mid-axillary line to the parasternal region over the fifth rib. Several inches of the rib are incised, and the ribs above and below widely retracted. Openings in the diaphragm must be closed. The entire pleural surfaces are wiped clean and the opening closed by careful adjustment of the tissues in layers. Drainage is not desirable and is not employed; in fact, it is positively dangerous. Gas and oxygen or chloroform with oxygen is the general anæsthesia used, but local anæsthesia may be employed satisfactorily. Ether must never be given. Blood transfusion is frequently given before or after the operation. Morphine is always freely given and camphor injected if necessary. Great care is taken to see that the patient never gets the opportunity of breathing cool air. Watch is kept subsequently to operation for the accumulation of fluid in the pleura, and puncture is performed daily to obtain the fluid for bacteriological examination. Increasing infection of the fluid is generally treated by the removal of one or two stitches and the insertion of a drainage-tube, but repeated aspiration has been successful in many cases. Duval has shown that the lung can be delivered on to the chest wall as intestine may be brought out of the abdomen.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—An ordinary meeting was held on Dec. 6th at the West London Hospital, when a paper was read by Dr. F. J. McCann entitled "Treatment of Some Common Ailments of Women." Dr. McCann first dealt with menstrual disorders, pointing out that frequently such are associated with abnormalities in secretion of one or more of the ductless glands. For amenorrhœa he often found small doses of thyroid extract, at times combined with ovarian extract, productive of quicker results than the usual treatment with iron and arsenic alone. For dysmenorrhœa he advised that everything should be done during the intervals to increase the patient's power of resistance. Brief reference was made to menorrhagia, climacteric disorders, hæmorrhages and discharges from uterus and vagina, together with the treatment of displacement for the latter, of which the best treatment was said to be prevention, the lecturer advocating routine examination six weeks after confinement.—The paper was discussed by the President, Dr. Drummond Robinson, Dr. F. G. Lloyd, Dr. Rickard Lloyd, Dr. Herbert Chambers, Dr. H. H. Sanguinetti, and Dr. J. F. Halls Dally.—Dr. Robinson held the opinion that amenorrhœa was in itself of but little consequence, the cause being far more important. In excessive menstruation he advocated calcium lactate in 30 gr. doses every other night with or without pituitary extract, as recommended by Dr. Blair Bell. For "erosion" of the cervix, in many cases surgical treatment was regarded by him as unnecessary, but if called for he found the old-fashioned cautery best.

Reviews and Notices of Books.

Details of Military Medical Administration. By JOSEPH H. FORD, B.S, A.M., M.D., Colonel, U.S.M.C. Second revised edition. Philadelphia: P. Blakiston's Son and Co. 1918. Pp. 816.

THIS book is fortunate in being introduced by a letter of Surgeon-General Gorgas, who hopes that every medical officer in the U.S. Service will furnish himself with a copy. It has been written to help the newly-joined medical officer to observe official technicalities. The keynote of the book is contained in the following sentence:—

"If a physician, however eminent in his profession but without preliminary training, is suddenly called upon to discharge highly technical administrative duties, the sick and wounded under his care will inevitably suffer because of his inability to secure the supplies necessary for their welfare, to utilise them to the best advantage, and to properly organise and discipline his personnel."

Although this statement contains a considerable amount of truth, it does not credit medical officers with the powers of initiative and adaptability which many have undoubtedly displayed during the War; nor does it take into account the existence of a trained body of men accustomed to deal with these matters. Colonel Ford displays considerable care throughout the book to acknowledge any assistance he has received, and to point out the source of his information. The chapter on the Regimental Surgeon, he states, was written almost entirely by Major Heflebower; on the Ambulance Company by Major McCornack; on the Field Hospital by Lieutenant-Colonel Reno; on the Camp Hospital by Lieutenant Simmons; on Hospital Trains by Major Hart; on the Base Hospital by Captain Kramer and Major Metcalfe; on the Department Surgeon's Office by Mr. Cleave; on Medical Supply Depots by Colonel Raymond and Major Wolfe. Even with this assistance the amount of work entailed by the preparation of the remaining 11 chapters must have been very considerable. The most interesting chapter of the book, that on the Evacuation of Sick and Wounded, is evidently written from Colonel Ford's actual observations of events in the field. Perhaps this chapter is the only one which contains much that is new to the average medical man who has served in the British Army. The chapter on Malingering is apparently a compendium of bulky quotations from the works of Allied and enemy writers; although useful, it cannot be read with the same satisfaction as the production of a capable writer with an all-round knowledge of the subject. A considerable amount of repetition occurs throughout the book; many of the regulations for a smaller hospital are much the same as those for a larger hospital, and yet both sets are given. Much of the book is taken up with details of office work. The book is undoubtedly of use to American medical men concerned with military administrative work; although much of the information contained in it is given in our small official publications, such as R.A.M.C. Training, and Field Service Regulations. But it will be well worth the while of the British medical officer to study those parts of the book dealing with active service in the field.

Syphilis, Paludisme, Amibiase: Traitement Initial et Cure de Blanchiment. Par PAUL RAVAUT. Paris: Masson et Cie. 1918. Pp. 88. 4 fr.

THE three protozoal diseases, syphilis, malaria, and dysentery, the treatment of which is considered in this little book, resemble one another, not only in some aspects of their pathology, but more especially in their stubborn resistance to eradicative treatment. That syphilis is not easily eradicated—i.e., cured—has long been recognised, but that malaria is incurable by quinine we have only learned during the war; in fact, too much in the past has been claimed for quinine. We now know that novarsenobenzol will do for simple tertian malaria all that quinine does, but certainly quinine and probably also novarsenobenzol alone will not cure simple tertian malaria. Again, emetine—excellent, apparently, in the initial treatment of amœbiasis—of itself fails to cure even by prolonged administration, though in the form of emetine bismuth biniodide in a large percentage of cases apparent cure is effected. The author is an advocate of combined treatment; for syphilis, mercury and novarsenobenzol for five years; for malaria, quinine and cacodylate of soda for two months; for dysentery, emetine and novarsenobenzol for 40 days, to be followed by 12-day courses monthly or bimonthly. How far two drugs similar in their action—e.g., quinine and novarsenobenzol in simple tertian malaria, emetine and novarsenobenzol in dysentery—are more effective than when either of the two is used singly carefully controlled experimental work alone can show. At present there is evidence in the diseases we are considering that this is so, but it will be some time before proof is furnished. It is fortunate that in malaria and dysentery direct proof is possible, and in syphilis we have the indirect evidence of the Wassermann reaction. For most diseases such proof is from the nature of the case not forthcoming and we are left in doubt whether an "elegant combination" of two drugs with similar action is any better than either of itself. The puzzling fact about the parasites of these three diseases is, How do some survive the drenching with the drugs which kill the others? Pathology or biochemistry is still silent as to this.

Dr. Ravaut's little book is clearly written, and the descriptions of the treatments are brief and practical.

James Hinton. By Mrs. HAVELOCK ELLIS. London: Stanley Paul and Co. 1918. Pp. 283. 10*s.* 6*d* net.

IN his dialogue "Symposium" Plato makes Aristophanes give his version of the primæval nature and state of man. The sexes were originally three, men, women, and the union of the two, having a name corresponding to this double nature, which once had a real existence, but is now lost, and the name is only preserved as a term of reproach.[1]

James Hinton, the subject of Mrs. Havelock Ellis's essay, would seem to have belonged to Aristophanes's third sex, for he was apparently compounded of man and woman, and we would add of a child. He was obsessed with the difficulties of sexual relations, and with the many undoubted hardships which women suffer in their sexual life, whether they are married or unmarried. Prostitution was to him a thing to be made impossible, but we doubt whether the remedy which we gather he proposed—namely polygamy—would be any real remedy. Polygamy existed side by side with prostitution among various ancient races, such as the Hebrews of the Bible, and the ancient Babylonians, just as it does to day among polygamous Mohammedans and Hindoos. But though Hinton was wayward, visionary, and, to our mind, hopelessly unpractical, yet he had in him at least a particle of that divine discontent which has always been a characteristic of reformers.

Lessons on Massage. By MARGARET D. PALMER, formerly Masseuse and Manager of the Massage Department of the London Hospital, and Instructor of Massage to the Nursing Staff; a Founder of, and Examiner to, the Incorporated Society of Trained Masseuses. Fifth edition. Illustrated. London: Baillière, Tindall, and Cox. 1918. Pp. x.–340. 10*s.* 6*d.* net.

SEVEN years ago we reviewed the fourth edition of this handbook, which is characterised by a clear and simple style, making it agreeable reading. The book being written for the student, the scheme followed is that of describing the anatomy of a part and then its treatment. But the medical man who reads its pages will not find this arrangement equally advantageous. He will also have to look elsewhere for help and guidance when directing the treatment of recent injury. The almost complete absence of reference to electrical and hydrological methods, and to the use of gymnastic and mechanical apparatus should be remedied in future editions. We must warn the student against allowing the schematic arrangement of the text to stereotype treatment unduly. A chapter on Swedish remedial gymnastics, which has been added to this edition, is one of the best epitomes of the subject in short space which we have seen.

Treballs de la Societat de Biologia. Any V., 1917. Barcelona: Institut d'Estudis Catalans, Barcelona.

THIS attractive volume of 365 pages records eight sessions of the Barcelona Biological Society—six held at the physiological laboratories of the Faculty of Medicine and one each at the gynæcological lecture theatre and the Institute of Sciences. The papers reach a high standard of interest, and a notable feature is an excellent series of coloured microphotographs illustrating histological points in various articles. A portrait of the society's founder, Dr. Enric Prat de la Riba, who died last year, appears as frontispiece.

THE LANCET.

LONDON: SATURDAY, DECEMBER 21, 1918.

The Practice and Teaching of Midwifery.

AN interesting series of articles appeared in the November number of the *Edinburgh Medical Journal* on the Teaching of Obstetrics and Gynæcology to Medical Students. They were contributed by teachers from Edinburgh, London, and Dublin, and on reading them we are driven to the conclusion that the present method of teaching these two important subjects is far from being satisfactory. The majority of the writers are agreed that it is a mistake to attempt to divorce midwifery from gynæcology, they are too interdependent; and while the present method of teaching gynæcology is perhaps sufficient for its purpose, the same is certainly not true of the teaching of midwifery. It is not possible, nor is it necessary, that the student on entering private practice should have any very extended knowledge of the diseases of women; he should be able to recognise the normal, and should be familiar with the commoner abnormalities, but beyond this his knowledge cannot extend. Experience will follow, and in the meantime counsel is readily available. In midwifery, however, the requirements of the young practitioner are quite different: at any moment he may be called upon to treat a grave complication of labour, and upon his ability to do so properly and skilfully may depend the lives of both mother and child. Acute gynæcological cases calling for immediate treatment or operation are rare; acute complications in labour threatening the life of the mother are not uncommon, and require for their recognition and treatment a complete and well-grounded knowledge of the subject.

If the time-tried methods adopted for teaching midwifery in Edinburgh are faulty it cannot be maintained that the methods in vogue in most of the medical schools in London are any better. A medical student immediately after attending a course of systematic lectures on midwifery may have to take duty in the extern maternity department, and while theoretically he is supposed to conduct his first case under the supervision and with the help of the extern maternity assistant, it happens not infrequently that he does so with the assistance only of another student knowing little more than himself; and, indeed, in some instances he has to attend entirely alone. At some hospitals he is required to act as clerk in the lying-in wards for a certain time before taking up duty in the extern department; but as in the case of most hospitals accommodation for their students is not available in the immediate neighbourhood, and as labour cases occur at any hour of the day or night, the student may never actually have been present even at a normal labour before taking charge of his first case in the district. If he is accompanied by the extern assistant, the latter is usually a recently qualified man with perhaps no aptitude for teaching, even if he has the necessary knowledge and experience, which usually he has not. By the time the student has finished his month's term of duty in the extern department he may have been present at a varying number—possibly 20, 30, or even 40 labours. If they have all been normal he may have had no teaching from anyone, and generally is not in a position to learn much for himself; he will have been unlucky, though the ease with which he has completed an important section of his education may betray him into thinking the reverse. If he has been really lucky he has had one or more abnormal cases, and has seen these delivered by the assistant in their own homes, or possibly after admission to the lying-in ward. It is extremely unlikely that he will have seen a single case conducted by anyone senior to an obstetric registrar, and only in very rare instances will he have had the advantage of a demonstration on a patient in labour by one of the obstetric physicians to his hospital. It is true that in recent years an attempt has been made to improve the teaching of midwifery by certain examining bodies insisting upon the attendance of students on a certain number of cases in the wards of a lying-in or general hospital. Here again, however, the main part, if not all, of the teaching at the actual confinements is done by junior assistants or registrars, and very seldom indeed by any member of the visiting staff. No one could pretend that this state of affairs is satisfactory; and, indeed, no one wishes to do so. It is certainly most unsatisfactory and requires prompt remedy. But what can be suggested to ensure that the student shall receive teaching of the same standard and by the same class of teacher in midwifery that he is accustomed to receive in medicine and surgery? With a continuance of the present conditions this, frankly, is impossible. Clinical teaching in medicine, clinical teaching in surgery, and surgical operations can all be arranged at a fixed time to suit the convenience of the teacher and the student. This is not so with a case of labour; only too often this occurs at a time when it is physically impossible, under the conditions obtaining at present, for any member of the visiting staff to attend, and when any teaching that is done must devolve upon some junior resident officer or a registrar. The teaching of midwifery in London, and indeed in most of the cities of this country, requires complete reorganisation. The fact must be recognised that while attendance in an external maternity department is well calculated to give the student confidence, the surroundings of the patient are entirely unsuited for proper teaching. Clinical instruction in midwifery can only be carried out in the well-appointed wards and theatres of a lying-in hospital, and to be done efficiently must be done by senior members of the staff with the knowledge and experience necessary to give such important teaching.

There is only one solution of the problem—the provision of lying-in hospitals in this country in

sufficient numbers on the model of the Rotunda Hospital in Dublin, officered by whole-time senior and properly qualified teachers resident in the hospital, whose services therefore can be obtained at any time. These whole-time teachers must be paid a salary sufficient to attract really good men, who must be supplied with all that they require for their teaching—whole-time paid assistants, properly equipped clinical laboratories in which they may be able to carry out research work, and in which all the pathological work essential to proper clinical teaching can be conducted. Every student must be required to go into residence so that he may take duty in the lying-in wards for at least one month, and his attendance on his cases must be under proper supervision and with the assistance of as good clinical teaching as at the present time he can obtain in medicine and surgery. Under the same roof he should be able to carry out his clinical work, not only in midwifery, but also in gynæcology, and no attempts should be made to separate these two subjects. Until properly equipped and officered hospitals for lying-in cases, with provision for the carrying on of a maternity and child-welfare department in close association, are provided in London, the teaching of midwifery will never be upon a proper basis, and the reproach that the science of midwifery has been woefully neglected, and that no research work of any value has been carried out in this subject by the London school for many years past, will continue to hold good.

Primitive Agents in Treatment.

FIRE, air, earth, and water have always been the chief agents of mischief, and HAHNEMANN might have claimed their influence in support of his homœopathic principle, for the same quartette, artfully applied, are the most generally useful remedial agents, and as such have largely come into their own during the past four years. Fire has superseded other methods of disinfection and disinfestation on a large scale in many war areas, and in the form of radiant heat has relieved the disabilities of wounds. Air has been the universal remedy of trench life, and has transformed vast numbers of anæmic men, rendered anæmic by a stuffy indoor habit of life, into the fit and sunburnt warrior. The rôle of earth, sinister in providing the source of horrible wound infections, has been to provide also the vaccines by which the same infections have been prevented. Water has played the leading part in the continuous irrigation of wounds, doubt existing in regard to many chemical agents whether they do more than add a therapeutic aroma. It is noteworthy that on these four primeval things the teaching of public health is built up, or at all events the arrangement of hygienic text-books. For in the near future, in which preventive and remedial treatment are to be more closely combined, physical agents are likely to reassert their place in therapeutics challenged by the fine chemicals industry. From the relief of symptoms medicine is steadily working back to the removal of the cause of the malady in the individual subject, and from this to the larger causes in groups, in communities, and in nations. Water especially has too long been despised as a therapeutic agent. NAAMAN found, as many others after him have found, that it looks too simple. But within our own time water has been vindicated again and again over against chemical agents in the reduction of fever, for which it has the inestimable advantage of being safe. Any patient may have an antifebrin idiosyncrasy, but tepid sponging offers no risks. The compulsory diversion of chemical agents to war-like purposes has led many medical men to fall back upon physical agents in treatment, we doubt not with permanent advantage.

It is in this sense that we construe the plea for the increased recognition of physical treatment raised by Dr. FRANK RADCLIFFE in our correspondence columns this week. He enumerates a portentous list of conditions which can be successfully dealt with by physical methods, and which, as a matter of actual experience, have been thus successfully dealt with during the war. Army discipline, applying physical methods, has done wonders in training men in speed, alertness, and agility, in raising muscular tone, and in giving confidence and that conscious sense of well-being attendant on robust health. Physical treatment can, Dr. RADCLIFFE contends, be of equal service in restoring the unfit to a state of fitness or, failing that, to the maximum point of utility. But Dr. RADCLIFFE adds, and we endorse, a grave warning against physical treatment falling into unqualified hands. Whether Government can prevent the public being gulled by quacks and charlatans we do not know, but undoubtedly the glowing career of the unqualified physical specialist would soon pale if the medical profession itself were to give the guiding hand in physical treatment of all kinds. The practitioner has, largely of his own free will, surrendered any say in these matters to those without scientific training, and the first requisite is to set our own house in order and to make sure that physical treatment is placed on a satisfactory scientific basis. This cannot be done without accurate knowledge and research, and a chair of hydrology at one of our leading universities would be the fitting commencement of such a reform.

The treatment of the disabled man gives an excellent opportunity of putting these principles into practice. France and Italy have already been to the fore in making physical treatment available on a large scale under medical supervision. The agricultural colonies at Port Villez, Juvisy, Martillac, Milan, Poscia, and Palermo have already proved the value of what Professor SILVIO ROLANDO, of Genoa, calls the veritable resurrection of the soldier doing the agricultural cure. In agricultural work a great variety of exercises is possible all day long, whereas mechanical devices are more limited in kind and duration. Great numbers can be treated in field work without requiring a little army of skilled operators, and the interest is kept up by nature and not killed by machines. Ordinary physical treatment is often carelessly carried out, motions without aim are repeated without energy, and soon forsaken as being without interest, or at all events leaving a sense of boredom and insincerity. A memorandum issued by the Village Centres Council[1] for the

[1] See Village Settlements for Disabled Men. A scheme to combine restorative treatment with industrial and social reconstruction. THE LANCET, 1917, ii., 692. The present address of the Village Centres Council is 5, Little College-street, London, S.W. 1.

Curative Treatment and Training of Disabled Ex-Service Men gives the following summary of the experience in France:—

Agricultural work as a method of cure requires close supervision by medical men who have made themselves experts. Experience in France has shown that the agriculture cure centre should be residential and in the country. The convalescent soldier cannot be trusted to take his farming at home; he works either too little, too much, or in the wrong way. Wounded men can be sent at an early stage from the hospital to supervised work in the fields. Many go to work with open wounds. It has been proved that suppurating wounds heal more quickly under open-air work than in hospital. Long-continued muscular contractions give the "deep massage" needed to force out waste and poisonous products. French surgeons, convinced by an examination of men cured by agricultural work, are now asking that men should be sent at once from the hospitals to the fields. Splinters of bone and foreign bodies in suppurating wounds are soon discharged when daily work is commenced. It has taken four years to find this out. Many men with small and superficial wounds of recent origin should go at once to the fields.

The centre which the Village Centres Council hopes shortly to open at Enham in Hampshire, whilst officially recognised by all relevant Government Departments, is yet largely based upon experience gained abroad in the agricultural cure. The treatment will be chiefly on physical lines, and combined with training also carried on under medical supervision. Room will be found for village trades and handicrafts, and for intellectual and artistic training for those who need them, but the chief feature of the Centre will consist in curative agricultural work in the open air. The Centre is obviously one adapted to assist in the most practical way the demobilisation of men for industries on the land. All those who value physical treatment will earnestly wish the Centre success.

Christmas.

THE public are rejoicing at the release of a moderate store of good things by Government Order through the festive season of Christmastide. The great Christian festival is rightly one of good cheer, and the present occasion particularly invites rejoicing at home, when the end of the vast struggle has come, though leaving the heavy burden of readjustment and the stimulating tasks of reconstruction. Sensible people will need no warning as to excesses, and the material falling away from old standards of plenty should remind all of the indecency of luxury at this period. Its danger must also be recalled. After a period of restraint indulgence is unusually dangerous to health. The food limitations of the war have taught many valuable lessons, which have brought home the evil of excess. The nation has behaved splendidly over these restrictions, and its health has been well maintained; surely it is not now to be jeopardised by lust. During the festive season we are promised a release of flesh foods, such as turkey and beef, the former requiring no coupon and the latter to be supplied on double ration allowances. The public will welcome these concessions, but will hardly need reminding that it would be folly to give way to indulgence after a course of compulsory training in abstinence. Let Christmas be a merry season but a wisely spent one. Let those whose lot has been more happy remember the countless homes where the prevailing spirit must be, at the great season of family gathering, one of irremediable loss.

Annotations.

"Ne quid nimis."

GERMAN CIVILIAN HEALTH.

DURING the war it has been difficult to gather unbiased information regarding the health of the civilian population of enemy countries. But some exact, if scanty, evidence is now forthcoming. At the instigation of the editor of the *Deutsche medizinische Wochenschrift*, Dr. Behla, director of the medical department in the Prussian Registrar-General's Office, has analysed the deaths attributed to heart disease and apoplexy during the years 1912 to 1917. Cardiac deaths rose from a total of 63,400 in 1912 to 76,000 in 1917, the increase being about 20 per cent. in the towns and 10 per cent. in the country. 1914 already showed a surprising increase on 1913 in the urban districts, where the stress of mobilisation was evidently very great. During the same six-year period deaths from apoplexy remained much more constant, a slight urban increase being balanced by a slight rural decrease. The maximum in both town and country occurred in 1915, and the following year showed a drop to below the normal. Dr. J. Schwalbe, in commenting on the figures, claims the great increase in heart failure as a war sacrifice, brought on by a combination of psychical stress, bodily fatigue, and lowered nutrition. In the same number of the journal he adverts to the grave risk of epidemic disease from the demobilising army, especially in the East, the danger being greatest in regard to venereal diseases. The situation in this respect has, he states, been rendered more acute by the partial relaxation of discipline after the revolution among the troops, who, largely under the influence of alcohol, gave way to sexual indulgence in greater degree than under normal military restraint. An Army Order has been issued instructing the examination of soldiers of all grades for transmissible disease before demobilisation. In the case of cholera, typhus, yellow fever, plague, or small-pox the discovery naturally precludes demobilisation altogether. The same is the case in regard to the usual notifiable exanthems. In the case of other infectious diseases, including suspects and carriers—and in this category come syphilis, gonorrhœa, and scabies—the men are isolated for treatment on their own express wish, but detention is not enforced. The ex-soldier's attention is then called to the risk of spreading disease among his family circle and to the need of keeping under medical supervision. These measures seem to us, as to Dr. Schwalbe, sadly inefficient, and a large dispersal of venereal infection among the civil population is to be expected.

THE COMPLEMENT-FIXATION TEST IN TUBERCULOSIS.

THE Wassermann test for syphilis was recently on trial in our columns; the similar test for tubercle needs no less a critical examination, and the exhaustive article by Dr. Edward Fidlar, Captain, C.A.M.C., on the Complement-fixation Test in Tuberculosis in our present issue raises many questions which deserve an answer, if answer can be given. Dr. Fidlar has carried out the test on 570 Canadian soldiers, and in so doing has investigated a number of bacteriological problems which have hitherto made this particular serological test

one of the most difficult to interpret, both pathologically and clinically. The earliest research on the subject largely centred round the difficulty of finding a sensitive antigen and one which at the same time would not confuse the issue with cross-fixation of complement in syphilis. Dr. Fidlar is in agreement with most recent workers in considering a suspension of living tubercle bacilli the most satisfactory antigen. With two slightly different methods he obtained 74 and 77 per cent. of positive reactions in active pulmonary tuberculosis. By means of slight modifications in technique he was able to increase this percentage, but the fact that the method gave 21·8 per cent. of positives in cases clinically not considered tuberculous suggested that increased sensitiveness was not altogether an advantage. Dr. Fidlar's careful work once more raises the question: Is the complement-fixation test of practical value in the diagnosis of tuberculosis? Up to the present it must be regretfully acknowledged that the earlier hopes of the bacteriologist in this direction have not been fulfilled. It is not sufficient to obtain a positive reaction in cases of active tuberculosis which are already obvious to simpler clinical tests. A serological test, if it is to be really useful, must help the physician in the diagnosis of incipient pulmonary tuberculosis, of bone and glandular tuberculosis; it must also differentiate between active disease and arrested and quiescent lesions; whilst finally it must be free from technical laboratory difficulties, such as cross fixation of complement. Perhaps this is too high a standard to demand of any serological test at present, but, unfortunately, the exigencies of the situation demand it. Judged by this standard, the opsonic index, the various tuberculin reactions, and a host of less common tests have been found wanting. It is therefore no depreciation of Dr. Fidlar's admirable piece of work—which has effectively consolidated the present position—to say that complement fixation has not yet given us, what we need, a reliable serological test in tuberculosis.

THE HYGIENE OF THE NOSE.

MORBID conditions of the upper respiratory tract play a large part—some authorities believe a predominant part—in the catarrhal diseases of urban life. Among school children, indeed, nine-tenths of prevalent illness has been credited to catarrhs. In spite of this, little is really known regarding the root causes of adenoids, atrophic and hypertrophic rhinitis, sinusitis, and hoc genus omne. All sorts of theories and explanations have been advanced, none of which has been found satisfying. It may well be that each of these conditions, as well as many others, is due to a specific infection. This is almost certainly the case with the common "cold in the head" where the virus is ultramicroscopic, and with atrophic rhinitis where the agent is the cocco-bacillus of Perez. In these and other similar inflammations nature attempts a cure by increasing the flow of mucus-carrying lymphagogues, which destroy the infecting organisms and neutralise their toxins. It is not very generally recognised that to a large extent these catarrhal infections are due to organisms which grow in the mucus on the surface of the membranes lining the air passages, and that it is their toxins which irritate the mucosa and cause it to inflame. The resulting swelling gives rise to obstruction, in which back-waters are formed wherein the microbes breed undisturbed by currents of fresh air, like the flies in the stuffy corner of a warm living room. To obtain a cure the first essential is to improve nasal ventilation and to make sure that all the recesses and pockets of the naso-pharynx are aerated. Nearly all the lower organisms are worried by currents of air. Secondly, an attempt should be made to improve the quantity and quality of the lymphagogues, this being presumably the way in which most antiseptics, vaccines, and the like, produce their effect. A nasal lotion or spray acts in both ways, partly by clearing the passages and partly by exciting the flow of mucus. In THE LANCET of Nov. 9th Dr. F. J. Woollacott suggested menthol inhalation as a form of nasal toilet combining both these factors. The nasal drill advocated by Mrs. Hancock is efficient in so far as it clears the passages, an important factor in young children, although not the whole story. Her especial merit rests on the emphasis laid on the direction of the clearing: "blowing down, not sniffing up" is her motto, and if she had her way children would be trained to the downward sniff from the tender age at which reflexes are still plastic.

A SMALL-POX OUTBREAK IN TEXAS.

THERE are two types of small-pox met with in the United States, the first, which is the most prevalent, being of a mild kind, with a case-mortality rate of about 1 per cent.; the second is of a more virulent form and commonly arises from imported infection, mainly from Mexico, where the disease is endemic, its fatality rate ranging from 20 to 30 per cent. The States on the Mexican border are much exposed to this imported infection, and Texas is one of the most frequent sufferers from it. A recent illustration of this is given in the *United States Public Health Reports* for Sept. 20th by Assistant Surgeon C. R. Eskey, of the U.S. Public Health Service. Eagle Pass, in Texas, is a small town with 6500 inhabitants, situated on the banks of the Rio Grande, which here forms the boundary between Mexico and the United States. Opposite, on the Mexican side of the river, is another small town, Piedras Negras, the two being connected by a bridge, guarded on the northern side by the U.S. Customs and other officials who examine all travellers entering Texas. But it is easy to ford the river unobserved at other points, and often infection is conveyed across the borders in this way. During 1917 small-pox was prevalent in Piedras Negras and its vicinity, about 1000 cases with 200 deaths coming under notice. Towards the end of 1917 the disease began to spread in Eagle Pass, where during the first three months of 1918 there occurred at least 150 cases, of which 33, or 22 per cent., died. There is a large Mexican population living in Eagle Pass, amounting to about two-thirds of the total inhabitants, living under conditions of considerable overcrowding. For instance, in a one-roomed hut there lived 15 persons, 9 of whom contracted small-pox. It was found very difficult to persuade the Mexican part of the population to be vaccinated, there being a strong belief among them that vaccination during an epidemic caused an outbreak of small-pox. The main incidence of the disease was upon persons under 15 years of age, among whom 103 attacks and 16 deaths were reported, while above the age of 15 there were 47 cases and 17 deaths. Thus the fatality rate among the first group was 15·5 per cent., and among the second 36 per cent. Concealment of cases was very frequent. Small-pox being comparatively common among the Mexicans, they regard it lightly notwithstanding its fatality.

and they therefore seldom seek medical assistance, contenting themselves with taking herbal remedies or patent medicines. They regard fresh air as detrimental to the patient, and consequently keep doors and windows closed during the illness. The neighbours consider it a duty to make frequent visits to the sufferers. Under these conditions it was not surprising that small-pox spread. Dr. Eskey mentions that at Eagle Pass dogs were blamed for conveying small-pox infection from one house to another. Most Mexican families keep one or more dogs, and these are the pets and playfellows of the children, frequenting the sick-room when any members of the family are attacked by small-pox or other diseases. The usual gravity of variola when it attacks a pregnant woman was noted, abortion resulting, usually with a fatal result. Dr. Eskey mentions several instances where second attacks of small-pox occurred. The circumstances of this outbreak are instructive and not without a lesson to ourselves in view of the possible occurrence of a small-pox epidemic when our soldiers return and the pent-up traffic of the past four years is liberated and begins to arrive at our ports from foreign countries.

A NEW SIGN OF SCIATICA.

AT a meeting of the Société Médicale des Hôpitaux of Paris on Nov. 11th Professor M. L. Rimbaud described a new sign of sciatica—effacement of the retro-malleolar fossæ. He referred to the importance of the region of the tendo Achillis in the diagnosis of sciatica. In addition to the reflex of this tendon, its sensibility to pressure and the lowered tone of the note obtained by percussing it are points to which attention has been drawn. In examining cases of sciatica and surgical lesions of the sciatic nerve at a military neurological centre, Professor Rimbaud has been struck with the peculiar appearance of the region of the tendo Achillis on the affected side. Instead of its normal appearance of a tense cord up to the point of insertion, the tendon was often less apparent and the two fossæ which separate it from the malleoli were effaced; the tendon appeared broadened, and the part œdematous. In the most typical cases the salient of the tendon disappeared, the retro-malleolar fossæ were no longer apparent, and the posterior part of the ankle took on a flattened characteristic appearance. This sign was especially observed in wounds of the whole sciatic nerve or of the internal popliteal. In medical cases of sciatica it was observed frequently; the more severe the disease the longer its duration. This sign was found in 70 per cent. of surgical lesions of the sciatic nerve and in 25 per cent. of medical cases of sciatica. Professor Rimbaud proposed for it the name "signe de l'effacement des gouttières rétromalléolaires," or, more simply, "effacement rétromalléolaire." He thought that it was simply due to loss of tone of the muscles of the calf, just as diminution of the gluteo-femoral fold is due to loss of tone of the muscles of the buttock. Such loss of tone, producing relaxation and depressibility of the tendon and, in certain cases, lowering of the heel, has been previously described. This relaxation effaces the retro-malleolar fossæ. Indeed, if the muscles of the calf be seized with the fingers and drawn upwards the effacement disappears. To observe this sign the patient should kneel on the edge of the bed or on a chair, as in examining the tendo Achillis reflex, or he should stand on a chair or table, so that the region of the tendo Achillis is well exposed.

THE ANNUAL REPORT FOR 1917 OF THE CHIEF MEDICAL OFFICER OF THE BOARD OF EDUCATION.

I.

IT is just ten years since the School Medical Service was established by law as a universal system in England and Wales. Sir George Newman's latest annual report, coming at the end of a decade of more or less experimental work and synchronising, as it does, with the cessation of hostilities in the great world war and with the passing into law of a new Education Act for England and Wales, which boldly enlarges the health activities of local authorities, is of necessity of more than ordinary interest and importance. It more than marks a milestone on the long road towards national health and efficiency. It at once closes a chapter of chequered experiment and heralds an era of more assured advance.

Retrospect.

Very properly, therefore, a section of the report is devoted to a review of the work of ten years, 1908–1917. The causes and conditions are recounted which led up to the legislation which brought the School Medical Service into being. It came at the end of a century of growing revulsion against the tragedy in respect of child-life which accompanied the industrial revolution in England. Already in 1908 the general problem was less one of rescuing the child from shocking and desperate conditions of hardship, cruelty, disease, and death, and more one of protection against disease, of building up the child's physique, and of providing such medical care and education as would lay the foundation of healthy childhood and adolescence. Two Acts had already been passed providing for the care and education of defective children, two official reports of investigations into the physicial condition of children of school age and their premature employment had been issued, and there were the reports of the Interdepartmental Committees on Physical Deterioration (1904) and on Medical Inspection and Feeding of Children attending the Public Elementary Schools (1905), the former of which first revealed the now obvious fact that the foundation of the public health rests upon the health of the child population. It is strange that Sir George Newman in his enumeration of the causes and events which led up to the passing of the Education (Administrative Provisions) Act does not include the Boer War and the amount of unfitness in the population which recruiting at that time revealed. This, to those of us who were then stirred by the necessity of improving the national physique, stands out as the one compelling factor. It was on a smaller scale a foreshadowing of the awakening to the need for reconstruction and effort which the great war now happily ended has brought about.

In the course of the review the machinery organised during the 10 years for the carrying on of the School Medical Service is described. A national system "as complete of its kind and more universal than elsewhere in the world" is at work in all the 318 educational areas of England and Wales. In 1915 (before the temporary depletion on account of the war) there were 1300 medical men engaged in the service. In 1917 a School Dental Service employing 200 school dentists had been established by 151 local education authorities out of a total of 318. In 1915 there were 1500 school nurses employed in 291 areas. Fifty-five authorities had made some arrangements for medical treatment in 1908, 279 in 1917. It is estimated that about 60 per cent. of the children found to be defective on medical inspection are receiving treatment. Taking London alone, the medical and dental provision in the 1910 scheme was for 2500 children; in the present scheme (1918–19) provision is made for 164,500 children.

The practice of physical training and the teaching of hygiene has since 1909 become universal in all training colleges and every educational area in England and Wales. In 1908 there were 304 special schools for blind, deaf, physically and mentally defective, epileptic, and tuberculous children, accommodating 17,610 children; in 1917 there were 413 similar schools, accommodating 31,470 children.

The maladies and disabling defects of many children are being put right which were formerly being neglected. Other substantial gains include the raising of the standard of cleanliness—beyond question the most paramount of hygienic needs, while profound educational results have brought

about a new understanding of the scope and opportunity of preventive medicine. Amongst these results are the influence upon the parent, the fuller appreciation of the individuality of the child, and the effect upon the methods and practice of education.

The experience of the ten years has shown that there has been an increase in the sense of responsibility of the mother, with the result that the child is better fed and receives more, rather than less, maternal care than formerly; the education authorities have found that, whatever may be attempted in the class-teaching of children in the mass, it is impossible to inspect, follow up, treat and care for the child except as an individual, and this discovery is exerting a deep influence upon the whole orientation of education. The far-reaching lesson has been learnt that it is primarily upon the child's physical and mental health that his welfare and upbringing depend.

Lest the reader should be too carried away by noting these advances the report hastens to add that the organisation is as yet incomplete in operation, inadequate in working and even in scope, insufficiently coördinated, and not yet yielding anything like its full measure of benefit. Particularly weak is the machinery in relation to anthropometry, a subject of national value and importance, and even such elementary auxiliaries as school baths, open-air schools, and adequate physical training are still, in most educational areas, lacking.

Sir George Newman in grave words states that it is incumbent upon him to say that the experience of a decennium has shown that the physical impairment of school children is wide in distribution, serious in degree, and grave in its effect upon adolescence and adult life. We profess to be astonished and depressed by the magnitude of the sickness claims upon the National Health Insurance, as well as by the large rejection of recruits; but we have been sowing the seeds of this harvest during long years of neglected maternity, neglected infancy, and neglected childhood, and long years of failure to organise or to understand adequately preventive medicine.

Medical Inspection.

The Code requirements are that provision must be made in every elementary school for the medical inspection of all children admitted to the school in the year, of all children between the ages of 8 and 9 years, of all children between 12 and 13 years of age, together with children over 13 years of age who have not already been examined after the age of 12. Normally on these requirements upwards of 2,000,000 children should be examined in the year; in 1917, however, the number was only 1,362,063. These figures suggest a decrease in the examinations of 31 9 per cent., due to curtailments consequent on the war.

In about 100 areas medical inspection was undertaken on the basis of "ailing children." The view of the London authority which experimented during 1916 with the examination of entrant children on an ailing basis was that the arrangement was unsatisfactory, because it failed to detect existing ailments. The Board endorses this view. "The School Medical Service is not a dispensary system; it is an educational system of preventive medicine."

The effects of the war in relation to the School Medical Service have been twofold. First, there has been serious disturbance of the machinery of the service, and, secondly, there has been anxiety regarding the depressing influences of war conditions upon the health of the children. Under the first heading there has been the depletion of the medical and nursing personnel on the staffs of the local authorities and constant changes militating against efficiency; many care committees are dissolved or in abeyance, and home conditions have been profoundly modified in some ways with a deleterious effect. Under the second head there have been apprehensions with regard to the suffering of the children from food rationing, high prices, lessening of parental control, daylight saving, and air-raids. It is satisfactory to learn from the report that there is a consensus of opinion that none of these has produced any ill results upon the children, with the reservation that parental preoccupation has led to an increase in uncleanliness and its associate conditions. Sir George Newman it is true, appears to accept the view that the Daylight Saving Act has, in some areas, deprived the children of an hour of sleep daily. Having given the impression that the effects of the Act in so far as they influence the health of the children are wholly bad, it would have been satisfactory if he had given more evidence in the support of this belief and discussed at least whether there were not countervailing advantages.

No doubt, resulting from the dislocation of the machinery of the service, there is no section of the report devoted this year to the findings of medical inspection throughout the country. Instead there is given the findings of a "control experiment" designed to check the results of previous examinations and eliminate as far as possible the disturbing factors inherent in a national system of medical inspection. Two sets of 300 unselected elder children, each in typical London and country schools, were inspected by one competent and experienced medical officer examining all 600 children on one schedule and by one standard. It was a "surprise" examination without notice or warning, including absent children as well as those in attendance at school, and had regard to the effect of the physical condition of the child on its education. The inquiry is reported in detail, and in order that the standards adopted should be better appreciated the report contains a brief description of the condition of a number of normal and defective boy and girl scholars.

The conclusions to be drawn from this control inspection are driven home by Sir George Newman with considerable force.

1. In the London group 7 per cent., and in the country group 10 per cent., of the elder children on the roll were absent from school on grounds of more or less chronic ill-health.

2. After deduction of the blind, deaf, mentally and physically defective and invalid children of this age-group, there were of the children present at school 21 per cent. found to be suffering from various defects "which interfere with their profiting to a due and reasonable extent from the educational facilities provided, and which will prevent them from playing their fair and proper part as citizens."

3. Of these elder children present at school 12 per cent. were ill-nourished; 19 per cent. were unclean in body; of the London children 40 per cent., and of the country children 65 per cent., had some carious teeth; 11 per cent. suffered from disease of nose and throat; 10 per cent. had "very serious" defects of vision, whilst another 13 per cent. had defective eyesight of slightly less severity; 6 per cent. suffered from defective hearing; of middle-ear disease there were 4 per cent. of sufferers.

4. Upwards of one-third of all these elder children are in London at least two or more years behind their normal school standard; there was a very definite accumulation of defective children of the higher ages in the lower standards, and physical defect appears to be one of the chief causes of backwardness in school.

5. The London children with sound dentition formed 60 per cent., the country children 35 per cent. The London children suffering from disease of nose and throat were 5 per cent., the country children 21 per cent. The London children furnished 2 per cent. of verminous heads, the country children 8 per cent. These differences would appear to be due, in the main, to the facilities of treatment, cleansing and supervision provided by the London County Council, which are not similarly available for the country children.

The number of children comprised in this model inquiry is not large, but the broad results are sufficiently close to those found on a large scale throughout the country to justify Sir George Newman in his comment that it seems futile to attempt to reform education apart from the physical condition of the child; that it seems unreasonable to expect healthy adolescence and healthy citizenship if we continue to neglect the remedy of the physical disabilities of childhood and the prevention of their cause.

Medical Treatment.

Speaking generally, the arrangements of the local education authorities for medical treatment have been maintained. In a few areas there has been a considerable extension of activities in 1917. 279 authorities made some arrangements for medical treatment, 231 provided school clinics, 95 contributed to hospitals, 223 made provision for supplying spectacles. On the contrary side, 87 authorities made no provision for treatment of minor ailments, 167 none for dental defects, 92 none for errors of refraction, 95 none for supply of spectacles, 208 none for treatment of enlarged tonsils and adenoids, and 234 none for treatment of ringworm (X rays). It is unsatisfactory to learn that there are still one-third of the children known to be in need of treatment who do not receive it.

Under the heading "Partially Blind Children" many interesting facts are given in relation to the establishment

of special schools for myopic children. It appears that more than 20 such schools now exist and that during the past year eight new schools of this character have been certified by the Board in London alone. At Bradford a scheme is in operation whereby it is considered that the myopia will, by special methods of instruction, be rendered stationary, and that after two years the affected children may return to the ordinary methods of instruction with safety.

Special prominence is given in the report to the arrangements for treatment of defective vision, of enlarged tonsils and adenoids, and of ringworm, but it is strange to find that otorrhœa is dismissed as a minor ailment unworthy of special note. Otologists, as well as school hygienists, are more and more recognising that in this condition we have one of the gravest dangers to the life of school children, one of the chief causes of educational incapacity in deprivation of hearing, and a frequent cause of chronic ill-health. Children with this disease are the despair of out-patient departments and school clinics alike, and it would be a welcome step if the Board of Education would take the lead towards the establishment of adequate provision for dealing with this disabling complaint, for which, in many cases, conservative operation involving in-patient treatment is the only means of cure.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Dec. 12th, Sir GEORGE H. MAKINS, the President, being in the chair.

The SECRETARY reported the death, on Nov. 21st, of Mr. Nottidge Charles Macnamara, past Vice-president and past member of the Council. The following resolution of condolence was carried:—

"That the Council hereby express their deep regret at the death of Mr. Nottidge Charles Macnamara, and their sincere sympathy with the members of his family in their bereavement. The Council do also record their appreciation of the many services rendered to the College by Mr. Macnamara as a Vice-president and member of the Council, and of the active part he took in professional and educational matters during a long and distinguished career in India and in this country."

A report was read from the Board of Examiners in Anatomy and Physiology for the First Fellowship stating that at the recent examination there were 36 candidates, and of these 15 were approved and 21 were rejected. A report was also read from the Court of Examiners stating that at the recent examination for the Final Fellowship held on Nov. 15th, 18th, 19th, and 20th there were 22 candidates; of these 3 passed, and it was resolved to grant diplomas of Fellowship to those qualified to receive it. The diploma of Fellow was conferred on:—

William Bashall Gabriel, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Middlesex Hospital, and William Edward Gallie, M.B. Toronto, Toronto University.

Captain John Isaie Keen, M.B. Lond., M.R.C.S., L.R.C.P., although successful in the examination, will not receive the diploma of Fellow until he has attained the age of 25 years.

Mr. V. Warren Low, surgeon to St. Mary's Hospital and lecturer on surgery to St. Mary's Hospital Medical School, was elected a member of the Court of Examiners.

The PRESIDENT reported the delivery by Mr. D'Arcy Power on Nov. 14th last of the Bradshaw Lecture on Cancer of the Tongue. The best thanks of the Council were given to Mr. Power for his lecture and he was requested to publish it.

A letter was read from Mr. S. H. Coplans asking, on behalf of himself and 14 other students of Guy's Hospital, the Royal Dental Hospital, and the National Dental Hospital (including six ex-Service men), that the following proposal be placed before the Council and Board of Examiners in Dental Surgery:—

"In view of the military situation and other circumstances that at present obtain that the February examination in the final subjects for the Licence in Dental Surgery of the Royal College of Surgeons be re-instituted."

The Council decided not to alter their decision to hold First and Second Professional Examinations for the L.D.S. only twice a year—viz., in May and December.

The Council proceeded to the consideration of a letter from the Board of Scientific Societies asking for the comments of the College in reference to the draft report of the Metric Committee of the Board. The Council decided to reply that they approved generally of the recommendations in the report of the committee.

The PRESIDENT reminded the Council that the Hunterian Oration was to be delivered by Sir Anthony Bowlby on Feb. 14th next.

THE Royal Dental Hospital, Leicester-square, has received a grant of £50 from the Corporation of the City of London.

The War and After.

THE CASUALTY LIST.

THE names of the following medical officers appear among the casualties announced since our last issue:—

Died.

Col. H. G. Melville, C.I.E., I.M.S., was educated at Edinburgh, and qualified in 1890. He held an appointment for some two years at the Edinburgh Royal Infirmary, and then entered the Indian Medical Service. Later he was attached to Lahore Medical College, where he was professor of materia medica. He saw service in 1894 in the Waziristan campaign and in 1897 in the Punjab and in the Tirah campaigns. In 1916 he was appointed consulting physician to the Mesopotamian Expeditionary Force, in connexion with which he was mentioned in despatches and awarded the C.I.E. He died at Baghdad.

Capt. J. M. Gage, R.A.M.C., qualified at Dublin in 1910, and held appointments at Mercer's Hospital, Dublin, and at Noble's Hospital, Douglas. At the time of joining the R.A.M.C. he was senior assistant medical officer at the Royal Earlswood Institution, Redhill, Surrey.

Capt. D. P. Lindsay, R.A.M.C., qualified at Edinburgh in 1912, and prior to joining up was in practice at Gateshead-on-Tyne.

Capt. G. E. Keith, R.A.M.C., qualified at Edinburgh in 1887, and was at one time assistant to the professor of clinical surgery at the Royal Infirmary, Edinburgh. Prior to going on active service he was in practice in Manchester-square, London, and was the author of several articles in the medical press, and of a text-book of abdominal surgery. He died in Italy of influenza.

Capt. D. Cotterill, R.A.M.C., was educated at Cambridge and at Edinburgh, and qualified in 1906. Prior to joining up he was in practice at Edinburgh, where he was assistant surgeon at the Royal Infirmary. He died in France of pneumonia.

Surg. Lieut. M. E. Jones, R.N., was a student at St. Thomas's Hospital, London, and qualified this year.

Capt. R. S. Armour, R.A.M.C.

Capt. J. Donaldson, R.A.M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Capt. G. E. Keith, R.A.M.C., died in Italy of influenza, youngest son of the late Dr. T. Keith.

Capt. D. Cotterill, R.A.M.C., died in France of pneumonia, eldest son of Lieut.-Col. J. M. Cotterill, C.M.G., R.A.M.C.

Capt. H. J. P. Creagh, Suffolk Regiment, died of wounds at Le Tréport, only child of Major S. H. Creagh, late R.A.M.C., of Haughley, Suffolk.

THE HONOURS LIST.

The following awards to medical officers are announced:—

The Victoria Cross.

Capt. BELLENDEN SEYMOUR HUTCHESON, Canadian A.M.C., attd. 75th Bn., 1st Central Ontario R.—For most conspicuous bravery and devotion to duty on Sept. 2nd, when under most intense shell, machine-gun, and rifle fire, he went through the Quéant Drocourt Support Line with the battalion. Without hesitation and with utter disregard of personal safety he remained on the field until every wounded man had been attended to. He dressed the wounds of a seriously wounded officer under terrific machine-gun and shell fire, and, with the assistance of prisoners and of his own men, succeeded in evacuating him to safety, despite the fact that the bearer party suffered heavy casualties. Immediately afterwards he rushed forward, in full view of the enemy, under heavy machine-gun and rifle fire, to tend a wounded sergeant, and, having placed him in a shell-hole, dressed his wounds. Captain Hutcheson performed many similar gallant acts, and by his coolness and devotion to duty many lives were saved.

Distinguished Service Order.

Capt. DAVID WILLIAM MCKECHNIE, 6th Fd. Amb. Can. A.M.C.—For conspicuous gallantry and devotion to duty. While preparing an advanced dressing station in a village, it was subjected to an intense bombardment, but he remained at his post dressing the wounded, and refused to take underground cover.

Major STANLEY GRAHAM ROSS, M.C., 6th Fd. Amb., Can. A.M.C.—For conspicuous gallantry and devotion to duty. On three successive days this officer was in charge of collecting posts and advanced dressing stations. He accompanied the stretcher-bearers in the advance, to see that proper touch was maintained. His coolness and disregard of danger under heavy fire had an excellent effect on the work of the bearer parties.

Col. ROBERT MILLS SIMPSON, Can. A.M.C., A.D.M.S., 2nd. Can. Division.—For conspicuous gallantry and devotion to duty in establishing, often under heavy fire, his advanced dressing stations and collecting posts, and personally superintending the evacuation of the wounded. When a sudden attack resulted in the capture of a village, he went up under fire and personally dressed the wounds of his men on the field, evacuating all by the evening. His tireless work undoubtedly saved many lives.

Second Bar to Military Cross.

Temp. Capt. (acting Major) ROBERT MASSON GREIG, M.C., 63rd Fd. Amb., R.A.M.C.—He displayed conspicuous gallantry and great devotion to duty in attending to the wounded and superintending their evacuation from advanced positions. To his admirable organisation and self-sacrificing endurance, working without rest or sleep, many wounded men owe their lives, and his coolness and courage when leading his stretcher-bearers forward under heavy fire were admirable.

Bar to Military Cross.

Capt. (acting Major) CHARLES STUART PEDDIE BLACK, M.C., 1/2nd (Low.) Fd. Amb., R.A.M.C., T.F.—For conspicuous gallantry and devotion to duty during an advance. Under heavy shell and machine-gun fire he reconnoitred the forward roads and brought up a tent subdivision and set up an advanced dressing station. By his energy and courage he was enabled to clear all wounded from the aid-posts and evacuate them to the main dressing station.

Capt. CHRISTOPHER MATHESON FINLAYSON, M.C., Can. A.M.C., attd. 20th Can. Bn., 1st C. Ontario R.—For conspicuous gallantry and devotion to duty. As medical officer of the battalion during an attack he did excellent work in attending to several wounded men under shell and machine-gun fire. His coolness and attention to duty, regardless of personal safety, were an inspiration to all.

Capt. (acting Major) WILLIAM MURDOCH, M.C., R.A.M.C., S.R., attd. 52nd Fd. Amb.—During three days' severe fighting he was untiring in his efforts, working night and day with his stretcher-bearers, attending to wounded in forward positions and evacuating them rapidly through difficult country. He was severely wounded in the arm by direct machine-gun fire, but insisted on carrying on his duties until he received a direct order from the commanding officer to report to a dressing station. His courage under fire and great endurance were splendid examples to everyone.

Temp. Capt. PATRICK JOSEPH O'REILLY, M.C., R.A.M.C., attd. 7th Bn., E. York R.—For conspicuous gallantry and devotion to duty in attending to the wounded under heavy fire during several days' operations. He advanced with the leading troops in an attack and brought in many wounded men from in front of the lines. He set an inspiring example of coolness and skill.

Temp. Capt. (acting Major) JOHN McLEAN PINKERTON, M.C., 13th Fd. Amb., R.A.M.C.—For conspicuous gallantry in charge of stretcher-bearers. He went forward with some bearer squads to bring in wounded which bearers had been prevented from getting to by machine-gun fire. He ultimately succeeded in bringing in some of the wounded, though fired on every time he was observed. Throughout the operations he showed the greatest zeal and devotion to duty. He was finally severely wounded.

Temp. Capt. (acting Major) WILLIAM KENNETH ARMSTRONG RICHARDS, M.C., R.A.M.C., attd. 55th Fd. Amb.—For conspicuous gallantry and devotion to duty. He followed up an attack under very heavy fire and organised and carried out the evacuation of the wounded during several days' operations with the greatest courage and skill.

The Military Cross.

Temp. Capt. PATRICK AUGUSTINE ARDAGH, N.Z. Med. Corps, attd. 1st Bn., Auckland R.—For conspicuous gallantry and devotion to duty. He worked in the open all day under very trying conditions, and at times under heavy fire. Hearing that the personnel of another battalion's aid-post had been blown out, he at once went to the place and worked for several hours under shell fire until he had cleared the wounded. By his energy and disregard for danger many lives were saved.

Capt. CHARLES FRANCIS ATKINSON, Can. A.M.C., attd. 44th Bn., Manitoba R.—For conspicuous gallantry and devotion to duty during an attack. Finding that heavy enemy machine-gun fire prevented any carrying back of casualties, he went forward and personally dressed a large number of casualties. Later, under heavy fire, he organised special parties and cleared all wounded effectually. He saved a number of lives.

Capt. GEORGE RAYMOND BABY, 4th Fd. Amb., Can. A.M.C.—For conspicuous gallantry and devotion to duty in charge of a stretcher-bearer section which he brought up immediately behind the infantry advance and collected the wounded. He was continuously exposed to every kind of hostile fire. His energy in searching for wounded resulted in his area of the battlefield being thoroughly and quickly cleared.

Capt. JAMES EVERETT BARRY, Can. A.M.C., attd. 2nd Bn., Eastern Ontario R.—For conspicuous gallantry and devotion to duty during a successful attack. This officer tended the wounded among the attacking companies under intense fire, dressing their wounds and directing them to the aid-post. He searched the field for wounded under full observation, and frequently under heavy fire of enemy. He must have saved the lives of many men who were lying in exposed positions.

Temp. Capt. ELLIS CAMPBELL BOWDEN, R.A.M.C., attd. 2nd Bn., Lond. R.—He attended to wounded men under a very intense fire from machine guns in daylight, and helped to carry many wounded into safety in full view of the enemy. His unceasing efforts and his self-sacrificing disregard of danger saved many lives, and were the admiration of all who saw him.

Temp. Capt. (acting Major) JOHN BURKE, 130th Fd. Amb., R.A.M.C.—During ten days' severe fighting he was unremitting in his devotion to duty, tending the wounded and selecting, often in the middle of the night, suitable places for his dressing stations. He displayed conspicuous courage and coolness under fire, and his initiative and endurance evoked the admiration of all who were with him.

Lieut. FINLAY CAMERON, R.A.M.C., Spec. Res., attd. 14th Bn., Welsh R.—During many days' hard fighting his courage and devotion to duty were conspicuous. He was continually at work under heavy shell and machine-gun fire attending to the wounded and organising their evacuation. He was wounded himself on one occasion, but remained on duty. His behaviour throughout was admirable.

Capt. ALEXANDER RAE CAMPBELL, Can. A.M.C., attd. 5th Bde., Can. Fd. Arty.—For conspicuous gallantry and coolness. When the battery came into action under heavy machine-gun fire a number of men were wounded. This officer collected and carried them to trenches, where he dressed their wounds, constantly under heavy fire. He set a fine example to the men round him at the time.

Lieut. HENRY ALEXIS CHODAK, R.A.M.C., Spec. Res., attd. 1/5th Bn., Lond. R.—For conspicuous gallantry and devotion to duty. He was wounded during an attack but refused to withdraw, and remained with the battalion for three more days attending to the wounded, often under heavy fire. He set a splendid example of determination.

Temp. Capt. ALFRED MACKENZIE CLARK, R.A.M.C., attd. 1st Bn., North'd. Fus.—For conspicuous gallantry and devotion to duty. Hearing that there were several wounded men lying out that could not be collected until nightfall, owing to snipers and machine-gun fire, he went himself and dressed them in the shell-holes where they lay. On this, as on other occasions, he showed a total disregard for his personal safety when the welfare of the wounded was at stake.

Capt. (acting Major) FREDERICK CLARENCE CLARKE, 12th Fd Amb., Can. A.M.C.—For conspicuous gallantry and devotion to duty. Under heavy shelling he collected four severely wounded men, dressed them, placed them under cover, and remained with them until help arrived, when he got all four away safely. For three days of heavy fighting his cheerfulness and devotion to duty inspired all under him.

Capt. WILLIAM JAMES DOWLING, R.A.M.C., Spec Res., attd. 3rd Bn., M.G. Corps.—For conspicuous gallantry and devotion to duty. He tended and evacuated wounded of his own and other units under very heavy shell and machine-gun fire. Later, he did excellent work in charge of the bearer section of a field ambulance. By his zeal and fearless conduct he saved many lives.

Capt. HARRY DUNLOP, Can. A.M.C., attd. 102nd Bn., 2nd Central Ontario R.—For conspicuous gallantry and devotion to duty. This officer followed close behind the attack and attended to the wounded under heavy machine-gun fire. He was untiring in his efforts to care for and evacuate the wounded, and undoubtedly saved many lives.

Capt. JOSEPH CULLODEN EAGAR, Can. A.M.C., attd. 78th Bn., Manitoba R.—For conspicuous gallantry and devotion to duty. Throughout the fighting this officer worked unceasingly, ministering to the wounded, frequently under heavy shelling and machine-gun fire. He went without food or sleep, and when wounded refused to leave until his station was cleared.

Temp. Capt. ORIE ELGIN FINCH, R.A.M.C., attd. 2nd Bn., K.O. Sco. Bord.—For conspicuous gallantry and devotion to duty. He moved his aid-post forward to close behind the front line under very heavy machine-gun fire. Here he worked unceasingly in a trench for thirty-six hours bandaging and attending to wounded; and it was due to his fearless conduct and splendid energy that all the wounded were attended to in a short time.

Capt. (acting Major) STANLEY RIDER GIBBS, 2/2nd (Wessex) Fd. Amb., R.A.M.C. (T.F.).—For conspicuous gallantry and devotion to duty. He organised the finding and evacuation of one officer and four other ranks lying wounded in an advanced machine-gun post in front of our lines, and although the operation, which took several hours, was conducted under almost continuous machine-gun fire, he recovered them all.

Temp. Capt. BASIL GRAVES, R.A.M.C., attd. 13th Bn., R. Fus.—For conspicuous gallantry during an attack. He dressed wounded in the open under difficult conditions, and frequently under machine-gun fire. Throughout the operation he encouraged the wounded by his cheerfulness and disregard of danger, and by his devotion to duty saved many lives.

Temp. Capt. WILLIAM HAMILTON, R.A.M.C., attd. 223rd Bde., R.F.A.—For conspicuous gallantry during an advance. He remained at the gun positions throughout the operations. Under heavy shelling he attended to wounded in exposed positions, and was always cheerful under most trying circumstances. His courage and devotion to duty won him the admiration of all ranks.

Capt. (acting Major) WILLIAM JAMES HIRST, 1st, attd. 2/1st, S. Mid. Fd. Amb., R.A.M.C. (T.F.).—For conspicuous gallantry and devotion to duty in organising the evacuation of wounded from a village during an enemy attack. He remained behind when the enemy advanced into the village and assisted in removing all the wounded, refusing to leave the village until the last man had been brought in. He has at all times shown great coolness and disregard of danger under heavy fire.

Tempt. Capt. JEREMIAH HOLLAND, R.A.M.C., attd. 1st Bn., Ches. R.—For conspicuous gallantry and devotion to duty. Under very heavy machine-gun and rifle fire he collected and evacuated wounded from a ridge. He showed utter disregard for personal safety, and by his zeal and energy set a splendid example to those under him, and saved many lives.

Capt. LANCELOT JOHN HUNTER, Austr. A.M.C., attd. 15th Bn., Aust. Infy.—For conspicuous gallantry and devotion to duty. When the battalion was heavily shelled in a bivouac for two hours he attended to the wounded with utter disregard of danger. During an attack he followed closely behind the attacking troops and attended to the wounded under heavy fire. He set a splendid example of self-sacrifice.

Capt. BELLENDEN SEYMOUR HUTCHESON, Can. A.M.C., attd. 75th Can. Bn., 1st Central Ontario R.—For conspicuous gallantry and devotion to duty. Before the battalion reached its jumping off position the enemy put down a heavy barrage and many casualties were sustained. This officer worked unceasingly in attending to and dressing the wounded under heavy fire in open ground. During the mopping up of a village he passed through the streets several times attending to the wounded. He also voluntarily dressed nearly 100 enemy wounded who had been left behind.

Capt. THOMAS ROSS JAGGER, Austr. A.M.C., attd. 31st Bn., Aust. Infy.—For conspicuous gallantry and devotion to duty. He carried on his work under heavy fire during two attacks and attended to the wounded of his own and other units with utter disregard of danger. He set a splendid example of courage and self-sacrifice.

Temp. Lieut. EDWARD DIGBY KINSEY, R.A.M.C., attd 1st Bn., Bedf. R.—For conspicuous gallantry and devotion to duty. He remained in the open for over an hour when the battalion were incurring severe casualties from intense shelling, dressing the wounded and seeing that they were promptly carried into safety. His efforts resulted in the saving of many lives.

Temp. Capt. ALEXANDER CHESTER LAMBERT, R.A.M.C., attd. 8th Bn., R. Lan. R.—For conspicuous gallantry and devotion to duty. He repeatedly established aid-posts during an attack and under very heavy shell and machine-gun fire attended and evacuated wounded belonging to his own and other units. When a shell struck his aid-post, killing assistants and slightly wounding himself, he remained at duty and refused to go down. Throughout the operations his conduct was admirable.

Capt. PHILIP WHITESIDE MACLAGAN, R.A.M.C., attd. 1st Bn. Herts R.—For conspicuous gallantry and devotion to duty. He continued to bind up wounded on a road under shell fire. He also showed great ability in getting wounded evacuated from the aid-post; and generally showed great coolness and disregard of danger under fire throughout the operations.

Capt. (acting Major) EDWARD BERTRAM MARSH, R.A.M.C.—For gallantry and marked devotion to duty during an advance. He kept touch with the regimental medical officers' and bearer divisions under very adverse circumstances and heavy fire, and so coördinated the forward evacuation that the divisional front was cleared in the shortest possible time. His energy was remarkable throughout the operations.

Capt. JAMES KILBURN MOSSMAN, 5th Fd. Amb., Can. A.M.C.—For conspicuous gallantry and tireless energy in the execution of his duty. This officer was in charge of a section of stretcher-bearers, and rapidly organised the evacuation of the wounded. He followed close on the attacking infantry waves, and regardless of his own safety attended to the wounded. His zeal and judgment were a great example to the men.

Capt. FINLAY MUNROE, Can. A.M.C., attd. 52nd Can. Bn., Manitoba R.—For conspicuous gallantry and devotion to duty in dressing and attending to wounded during a hostile barrage. This officer has always disregarded personal danger, and has undoubtedly saved many lives on the battlefield.

Capt. (now Maj.) SYDNEY MICHAEL O'RIORDAN, Austr. A.M.C., attd. 13th Bn., Aust. Infy.—For conspicuous gallantry and devotion to duty. During the later stages of an advance, when the infantry were under heavy fire, he established his aid-post in an advanced position and dealt very rapidly with the casualties. His initiative and coolness under heavy fire were an inspiration to all who came in contact with him.

Temp. Capt. ANDREW FINLAY READDIE, 21st Fd. Amb., R.A.M.C.—For conspicuous gallantry and devotion to duty. While supervising the evacuation of the wounded from the front line he heard that a medical officer in charge of stretcher-bearers had been killed. He at once proceeded to the spot through heavy enemy barrage and took charge of the bearers, and it was due to his prompt action that no delay resulted. He has consistently done good work.

Capt. LOUDON CORSAN REID, 12th Fd. Amb., Can. A.M.C.—For conspicuous gallantry and devotion to duty. For several hours under heavy rifle and machine-gun fire he dressed and cleared wounded, and by his efforts saved many lives. He several times went forward to points of extreme danger to satisfy himself that all wounded had been cleared.

Temp. Capt. JOHN JOSEPH REYNOLDS, R.A.M.C., attd. 15th Bn., Hamp. R.—For conspicuous gallantry and devotion to duty. He formed an advanced regimental aid-post on the side of the road, thus shortening the stretcher-bearers' journeys. Eventually he was forced to evacuate this position owing to hostile fire. Later, he dressed and attended to all the casualties of three battalions, though partially gassed himself. By his untiring energy he undoubtedly saved many lives.

Capt. FRANK ELLIOT TRENOWETH TRUE, Aust. A.M.C. attd. 48th Bn., Aust. Infy.—For conspicuous gallantry and devotion to duty. He moved forward with the assaulting troops under very heavy fire, established his aid-post and organised his stretcher-bearers, and was the means of saving many of the wounded. He carried out his duties under heavy fire with great skill and courage.

Capt. FRANCIS LOUIS TRINCA, Austr. A.M.C., attd. 2nd A.L.H.R.—For conspicuous gallantry and devotion to duty. During an attack this officer, although suffering from fever, carried out his duties with great energy and total disregard of danger. Later, he accompanied the troops in a counter-attack, attending to casualties in the open under fire, and setting a fine example of endurance.

Capt. ALBERT HENDERSON WALLACE, 13th Fd. Amb., Can. A.M.C.—For conspicuous gallantry and devotion to duty. While in charge of five stretcher squads he followed a battalion into action and established collecting-posts for the wounded directly behind the battalion. His courage and initiative enabled the wounded to be got out rapidly, thereby saving many lives.

Capt. WILLIAM CHARLES WALSH, 13th Fd. Amb., Can. A.M.C.—For conspicuous gallantry and devotion to duty. With four squads of stretcher-bearers he followed the battalion into action and established collecting-posts a few hundred yards behind the front line. He dressed and evacuated wounded under heavy shell fire, working all day and night in the open until all were carried off the field. He behaved splendidly.

Capt. ERNEST HAROLD WHELPLEY, Can. A.M. Corps., attd. Hdqrs., 3rd Bde., Can. Gar. Arty.—For conspicuous gallantry and devotion to duty. He at once went to a battery which was being heavily shelled, and as casualties occurred dressed their wounds and superintended their evacuation. He showed great coolness and devotion to duty.

Temp. Capt. WILLIAM BROCKIE WILSON, R.A.M.C., attd. 1st Bn. Devon R.—For conspicuous gallantry and devotion to duty. He treated the wounded of his own and other battalions; this involved passing backwards and forwards over shell-swept areas. Later he went forward with his stretcher-bearers and searched all the ground up to the front line. He showed splendid zeal and disregard of danger, and set a fine example to those under him.

Capt. PAUL ERNEST VOSS, A.A.M.C., attd. 58th Bn. Aust. Infy.—For conspicuous gallantry and devotion to duty. He worked at his aid-post under heavy fire throughout two days' operations, and attended to the wounded of two divisions. He set a fine sample of courage throughout, and undoubtedly saved many lives.

The following awards are in connexion with operations in the White Sea and in the Adriatic respectively:—

Distinguished Service Order.

Surg. Lieut. JOHN GREENLAW DOBSON, R.N., H.M.S. "M25."—Though wounded by the explosion of a shell, he carried out all operations that could be effected on the wounded, working continuously from 7 P.M. till 10 P.M., when he collapsed. Throughout this time Surg. Lieut. Dobson went about his work as if nothing had happened.

Surg. Lieut.-Cdr. CYRIL VERITY GRIFFITHS, R.N.

FOREIGN DECORATIONS.

French.

Legion of Honour.—Commander: Surg. Vice-Admi. Sir W. H. Norman, K.C.B. Chevalier: Surg. Cdr. W. W. Keir, C.M.G., R.N.

OBITUARY OF THE WAR.

JOHN DOW, M.B., CH.B. ABERD.,

CAPTAIN, INDIAN MEDICAL SERVICE.

Captain J. Dow, who died at Shiraz, Persia, on Nov. 5th, at the age of 29 years, was eldest son of Peter Dow, headmaster of the West End School, Elgin. He was educated at his father's School, Fordyce Academy, and the Elgin Academy, and graduated with distinction at Aberdeen University, taking the M.A. degree in 1910 and the M.B., Ch.B. in 1915. He was then house surgeon to Professor J. Marnoch at Aberdeen Infirmary, and before going to India in 1916 held a commission in the R.A.M.C., being attached to the Highland Casualty Clearing Station at Aberdeen. Captain Dow had performed valuable work in India, Mesopotamia, and Persia, spending 18 months at Shiraz, where he was actively engaged in combating the cholera epidemic. His death was due to influenza.

FRANK CECIL HARRISON, M.R.C.S. ENG., L.D.S.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain F. C. Harrison, who was killed in action in Belgium on Oct. 13th, at the age of 26 years, was eldest son of the late Frank Harrison, M.R.C.S., L.D.S., of Sheffield. He was educated at Sheffield Grammar School and King Edward VII. School. He then studied dentistry at the Royal Dental Hospital, London, and attended Sheffield University as a medical student, taking the diplomas of the Conjoint Board in 1915. An enthusiastic worker in the Officers Training Corps at the University, he obtained the Coronation Medal in 1911. He was gazetted in August, 1914, joined the R.A.M.C. after qualifying, and went out to France in 1915. At the time of his death he was attached to the Duke of Wellington's Regiment in the 49th West Riding Division. The A.D.M.S. of his division writes that he was able in his work and keen in all that pertained to the well-being of his men. "He was brave as a lion and a true friend to us all."

MENTIONED IN DESPATCHES.

In a despatch received from the Commander-in-Chief of the British Forces in Italy, dated Nov. 15th, 1918, the following reference to the medical services occurs:—

The fresh influenza epidemic, which broke out shortly before the commencement of the operations, threw a heavy and additional strain on the medical services. Despite this the evacuation and care of both the sick and wounded were rapidly and satisfactorily carried out. All the arrangements were most ably organised by my Director of Medical Services, Major General F. R. Newland, C.B., C.M.G.

In connexion with operations in the Sudan the name of Major A. Gibbon, R.A.M.C., is brought to notice for distinguished and gallant service in the field.

The names of Surg. Lieut.-Cdr. W. E. Ormsby, R.N., and of Surg. Lieut. L. F. Strugnell, R.N., have been mentioned in despatches dealing with operations in the Adriatic.

Correspondence.

"Audi alteram partem."

THE VALUE OF PHYSICAL TREATMENT.

To the Editor of THE LANCET.

SIR,—The Prime Minister in his speech on Nov. 16th, in placing the case for the Coalition at the Central Hall, Westminster, said: "The health of the people must especially be the concern of the State. This is one of the war's revelations." Might I be allowed to express in your columns my views regarding the adoption of physical treatment in a State scheme of medical service?

During the past four years physical treatment in all its branches has made great progress; it has been universally adopted, and the War Office in 1915 recognised the important rôle it plays in the treatment of men who are suffering from the many after-effects of disabilities contracted in the war. Dr. Fortescue Fox and others have, through the Royal Society of Medicine and other channels, left no stone unturned in their endeavour to inform the profession what could be done in this country and what was being done in other countries. Its adoption has been to a very large extent in conjunction with orthopædic treatment, and most of the institutions where these cases are treated possess complete physical treatment installations. Cases pass from the surgical or medical sides of a hospital to the after-treatment or physical treatment department, and remain there until no further improvement can be attained.

I should like to enumerate a few of the conditions which can be successfully dealt with by these methods—viz., hydrology, electricity, massage, exercise (active and passive).

1. Debility from any cause, e.g., pneumonia, typhoid, dysentery, all post-operative conditions, e.g., appendicitis, hernia, &c.
2. Rheumatism, including myositis, myalgia, fibrositis, rheumatoid arthritis, osteo-arthritis, both in the earlier stages.
3. Neuritis, including neuralgias of all kinds, particularly headaches, which are often of rheumatic origin due to fibrositis of the cervical muscles.
4. Nervous conditions, including neurasthenia, loss of nerve tone, general tremors and insomnia associated at the present time with the overstrain of war and shell shock.
5. Heart conditions, particularly arrhythmia, tachycardia, bradycardia, loss of myocardial tone; dilatation whether associated with valvular disease or not.
6. Post-operative conditions, such as adhesions following abdominal operations, contracted scars producing deformity by the trapping of nerves or tendons.
7. Fractures with only fibrous union; in other words, deficiency of callus.
8. Paralysis and paresis of any nerve, more particularly facial, ulnar, median, musculo-spiral, sciatic and branches.
9. Synovitis and fibrous ankylosis of large or small joints where breaking down of tissue and re-education of movement are necessary.
10. Circulatory conditions, such as trench feet, post frost-bite, and erythromelalgia.

There are many other conditions which might be mentioned where physical treatment is indicated. It is the accurate and direct therapeutic application of exercise in its many forms which is absolutely necessary to ensure a scientific and well-balanced method of procedure. Most of the men in our Army have been brought under discipline for the first time in their lives, and training in speed, alertness, agility, the strengthening of flabby and weak muscles, all combine to give them a feeling of well-being, confidence, and fitness to which they have been strangers.

Professor Tait McKenzie, of Pennsylvania University, who has served as a Major in our Royal Army Medical Corps, in taking part, on his return to America, in a discussion on a paper concerning the Reconstruction and Rehabilitation of the Disabled Soldiers, says:—

"In the inspection of training camps (in the early days of the war), which ran from 30,000 to 80,000 men, it was my duty to travel from one to the other, and we repeatedly found a number of men who were unable to take full training. Now these were paraded, and in the course of examination we found that many of them were suffering from conditions that could be cured by proper treatment, sometimes by operation, but more frequently by some form of physical therapy that would bring them back to military usefulness. The number of these was very considerable."

During the past two and a half years 10,000 officers and men have been treated by physical therapy in the department of which the writer has charge. Of this number 45 per cent. have finally been passed fit. These statistics show what physical treatment can accomplish in restoring the unfit to a state of fitness or, failing that, to the maximum point of utility. I trust that the authorities who formulate the scheme of State medical service will bear in mind the important rôle played by this form of treatment. It will certainly replace many bottles of medicine and benefit the patient by Nature's remedies. But I would emphasise that the application of physical therapeutics to pathological conditions must depend for its success upon careful selection and accuracy of the dose employed, and also on persistence in following a course of treatment. It is the neglect of these considerations which is responsible for most of the failures in their application. The physician often fails to appreciate the range and effectiveness of the most powerful and versatile system of therapeutics which is always at his command.

I should like to say that there is a very grave danger of this form of treatment falling into unqualified hands, and I beg to suggest that the Government should take steps to prevent quacks and charlatans from gulling the public by unprofessional advice and unskilled treatment. At present there is no law to prevent these individuals from opening elaborate treatment rooms and advertising, and thereby gaining distinct and unfair advantage over the qualified practitioner.—I am, Sir, yours faithfully,

FRANK RADCLIFFE,
Western Command Depôt, Heaton Park, Manchester. M.O. 1/c Treatment.

ADVANCES IN THE TREATMENT OF FRACTURES.

To the Editor of THE LANCET.

SIR,—Having seen in THE LANCET of Dec. 14th Dr. R. Scot Skirving's description of his visit to No. 8 Stationary Hospital I would like to add my appreciation of the work that has been done there. Personally I do not believe that any man has afforded the wounded soldier more freedom from physical anguish than Major M. Sinclair has. On the occasion of my last visit to that hospital in November I was much struck by the excellent series of specimens illustrating the various fractures of bones resulting from projectiles. These were beautifully mounted and the innumerable comminuted fragments were collected and secured in position with perfect accuracy. They will make a valuable addition to a collection such as the Keogh War Museum at the Queen's Hospital at Sidcup. The cases in the wards showed how it was possible by the proper use of glue and by other means to obtain accurate axial continuity of fragments, even in the worst cases of comminution. They illustrated the importance of leaving as many fragments as possible in the wound, since they served after a time to make abundance of new bone. Perhaps one of Major Sinclair's devices which has proved most effective and painless is the use of screws inserted into the long bones. These afford secure holds on which traction can be readily exerted. At this hospital the accuracy of Sir Almroth Wright's view is fully borne out by the use of dry gauze dressings, no antiseptic having been employed for over two and a half years. It must be a great source of satisfaction to British surgeons that their fellow countryman has been able to do so much for surgery by putting it upon a definite scientific basis. If one were asked to allot credit for the work done by British scientists and surgeons in this war I would conclude that that of Sir Almroth Wright has been of the greatest scientific importance to surgery, and that of Major Sinclair of the highest clinical value to the wounded soldier.

I am, Sir, yours faithfully,

Dec. 14th, 1918. W. ARBUTHNOT LANE.

THE LONDON UNIVERSITY ELECTION: A PROTEST.

To the Editor of THE LANCET.

SIR,—You have very justly placed our postcard below Sir Wilmot Herringham's angry letter of protest in your last Friday's issue, and it will be seen that we simply point out the probability that the medical candidate, not being a

graduate of the University of London, will only alienate votes from the Coalition candidate, which on public grounds we should greatly deplore. From his letter it might be feared that if he were returned Sir Wilmot's methods of controversy, whilst adding to the liveliness of the House, would scarcely enhance the dignity of his adopted University.

I am, Sir, yours faithfully,

London, Dec. 14th, 1918. R. DOUGLAS POWELL.

SPINAL ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—Owing to the demands upon your limited space, my remarks at the meeting of the Section of Anæsthetics of the Royal Society of Medicine, as reported in THE LANCET of Dec. 14th, have been necessarily abbreviated, and two points which I think are of some importance have been omitted. I should like to be allowed to refer to them.

The first point is that there has been a misconception of the nature of the two solutions commonly employed in spinal anæsthesia. The specific gravity of Barker's stovaine-glucose solution is 1·023, that of the stovaine-saline solution 1·083. The former, however, has always been called the "heavy" solution, the latter the "light" solution, and has been used as a "light" solution, the patient being placed very soon after injection in the head-down position. The fall of blood pressure being largely compensated by gravity, pallor, sweating, faintness, and collapse have been less frequent and less severe, and Barker's solution has been gradually ousted from its former position of predominance. Gravity can, however, be made use of with advantage when Barker's solution is injected. Diffusion plays a much smaller part in the production of disquieting or alarming symptoms than was originally thought.

The second point is that blood-pressure readings should be taken almost as a routine in spinal anæsthesia. They throw much light on the difficulties of the method, and are valuable in helping the anæsthetist to form a prognosis.

I am, Sir, yours faithfully,

FRANCIS E. SHIPWAY.

Queen Anne-street, W., Dec. 16th, 1918.

HÆMATEMESIS AS A COMPLICATION OF APPENDICECTOMY.

To the Editor of THE LANCET.

SIR,—In THE LANCET of July 6th there is an article by Dr. E. Drybrough-Smith on hæmatemesis as a complication of appendicectomy. I have had two cases following appendicectomy similar to the case he records, but, unfortunately, with not the same happy ending.

CASE 1.—I was called to see a patient, 19 years of age, suffering from appendicitis; with rest in bed, she got better. About three months afterwards she had a similar attack, which likewise subsided, and to prevent future attacks she desired an operation. On Oct. 18th, 1914, she went into a nursing home. The next day menstruation commenced, and as there was no urgency the operation was postponed until the 29th. During the interval of waiting in the home she was on full diet, under observation, and did not complain of any abdominal pain. This is important, because the question of gastric ulcer might arise in a girl of 19.

On Oct. 29th I removed her appendix; there were a few adhesions, but there was no difficulty whatever about the operation. She was put to bed in good condition. About eight hours after the operation I was called to see her, as she did not seem to be doing well. She had a very fast pulse, was very pale and very restless, and was evidently suffering from hæmorrhage. Though there was no swelling or discolouration about the wound her condition pointed so strongly to hæmorrhage that she was given an anæsthetic, and the wound was reopened, for fear a ligature had slipped, but everything was found in order. About four hours afterwards she vomited a large quantity of coffee-ground vomit; she was given a hypodermic injection of morphia and atropine and teaspoonfuls of water containing 10 minims of adrenalin extract every half hour. This treatment did no good, and she kept vomiting the same kind of vomit, and died about 24 hours after the operation.

Case 2.—In September, 1916, when surgeon with the French Red Cross, I was asked by a French colleague, a physician, to see a little girl, 10 years of age, whom he was treating for appendicitis. A diagnosis of appendicular abscess was agreed upon, and she was taken to a military hospital for operation. I found a big abscess in which there was a gangrenous appendix; a portion of omentum was also gangrenous. This and the appendix were removed. A large cigarette drain was put in the abscess cavity and the child returned to bed. in a much better condition than before operation. About six hours after the operation the night sister who had charge of the child sent for me. The child was very restless and very pale and was clearly suffering from hæmorrhage; there was no blood escaping from the drain, but to make sure there was no hæmorrhage at the site of operation the wound was reopened, but there was no sign of bleeding there. About 12 hours after the operation she brought up a large quantity of coffee-ground vomit, and continued vomiting until she died 16 hours after the operation. In neither case could I get a post-mortem examination.

Osler, in his text-book, mentions operations in the abdomen as being a cause of hæmorrhage of the stomach, particularly when the omentum is wounded. He also states that many cases have followed operations for appendicitis, the complication being very fatal. There is an article in Moynihan's "Abdominal Operations" on post-operative hæmatemesis in which many theories are mentioned as to the cause. He states that, as a rule, the amount vomited is small—this was not the case in the two patients I have seen. The question is also discussed in Keen and Da Costa's "System of Surgery," in an article by Van Hooke and Kanavel.

The consensus of opinion seems to be that the hæmorrhage arises from small erosions in the gastric mucosa. If I ever have the misfortune to meet another case I should try hypodermic injections of serum. Serum is a useful adjuvant in cases of hæmorrhage.

In a case I saw recently of severe epistaxis, in which oozing persisted after plugging the posterior nares with plugs soaked in adrenalin, the bleeding ceased after an injection of antidiphtheritic serum used in lieu of plain serum.

I am, Sir, yours faithfully,

J. VERE ARKLE, M.D., F.R.C.S.

Kalgoorlie, Western Australia, Oct. 9th, 1918.

THE CAUSES AND INCIDENCE OF DENTAL CARIES.

To the Editor of THE LANCET.

SIR,—Dr. J. Sim Wallace begins the introduction to his book on the Prevention of Dental Caries as follows: "Dental caries is one of the most easily and certainly preventable of diseases." Is this true? If so, it is a scandal that the details of its prevention are not known to every father and mother in the civilised world. It is impossible to exaggerate the terrible state of the teeth in this country, the disease and economic loss following the dental caries.

I urge you, Sir, to demand a Government Commission to inquire into the matter at once. This is what the President of the Dental Association of New Zealand said to the Acting Premier last July: "The examination of thousands of school children in New Zealand shows the percentage of those suffering from dental caries to be 95. If cows were similarly affected they would not be tolerated for one month." It is my firm belief that Dr. Sim Wallace has solved the problem.

May I point out that three articles of food, which taken in large quantities are believed to be most pernicious, have been very scarce as regards the first two, unobtainable as regards the third—i.e., (1) milk; (2) manufactured sugar and sweets; (3) soft white bread and finely milled flour in biscuits. Cow's milk belongs to the calf, and milk is the correct food for the toothless young only. Manufactured sugar, in the enormous quantities consumed before the war, is a modern article of diet; previously we made our own sugar. There is all the difference between the native grinding and chewing the cane for his meal and the concentrated article in the sugar-basin. Wholemeal bread *must* be well chewed; it cannot be bolted like the soft white of pre-war days. How are the children to-day? Apart from influenza, which is prevalent throughout the world, their health is excellent. Mr. H. J. Morris, in a letter to THE LANCET dated April 2nd, 1918, states: "It is easier and cheaper to feed children on preventive lines than as they are generally treated." The matter cannot rest where it is to-day. Are we to teach the public prevention, which costs nothing, or are we to supply an army of dental surgeons to fill the teeth of the whole community?

In my lectures to the soldiers under my care on "Why Does the Tooth, the Hardest Part of the Body, Rot in the Nursery and the Schoolroom?" I have pointed out that I never saw a case of appendicitis amongst the poor country Arabs under my care in Egypt before the war; that no girl ever came to me with a history of indigestion and subsequent gastric ulcer; that cancer, which so often attacks some part of the alimentary canal, was practically unknown to me; that tonsils and adenoids never came my way, the last possibly because practically all the children were breast-fed.—I am, Sir, yours faithfully,

W. E. NICKOLLS DUNN,
Horton War Hospital, Epsom, Dec. 7th, 1918. Major, R.A.M.C.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

Temp. Surg.-Lieut. C. K. Scales, who has been invalided on account of ill-health contracted in the Service, to retain his rank.

ARMY MEDICAL SERVICE.

Col. D. M. O'Callaghan, C.M.G., is placed on retired pay.

Headquarters of Administrative Services and Departments.

Temp. Major G. O. Taylor, Canadian A.M.C., to be Deputy Assistant Director of Medical Services.

ROYAL ARMY MEDICAL CORPS.

The undermentioned to be acting Majors: Capt. J. E. Hepper; Temp. Capts. H. G. Drake-Brockman and B. Sweeten whilst specially employed.

Temporary Lieutenants to be temporary Captains: S. F. Greenfield, P. S. Humm, H. W. Knowling, C. W. Joynt, L. H. Butler, F. W. H. Pilot, B. W. H. Fergus, J. G. Millar, J. C. Fox, H. S. Metcalfe, J. A. M. Bligh, G. T. Wrench, H. J. V. R. Allin, D. MacK. Gray, R. J. G. Halden, J. A. Johnstone, F. W. Lawrence, L. A. Morris, R. N. M. Rowstrom, D. B. Wilson, H. L. W. Woodroffe, R. Steel, B. E. Lawrence, A. R. P. Scott, H. Thomson, T. M. Hopgood, J. C. Johnson, G. C. Cossar, F. J. Power, G. Ferguson, R. O'Connor, H. S. Gabb, W. Crerar, F. C. Watson, E. Bottomley, W. Leathgarbarrow, E. A. B. Poole.

T. B. Sellors, late temporary Captain, is granted permission to retain that rank.

Officers relinquishing their commissions: Temp. Capts. J. D. Lithgow, H. C. Will, N. W. Walmsley, A. Griffiths (acting Major), D. R. Pike, H. C. Harper, H. A. Mason, G. P. White, A. Tait, H. A. Easton, H. Angel, F. W. K. Lawrie, A. C. Reid (and is granted permission to retain his rank); Temp. Lieuts. M. F. Tylor, C. I. Harmar.

TERRITORIAL FORCE.

Capt. (acting Major) G. T. Willan, D.S.O., is granted the pay and allowances of his acting rank.

General List.—Lieut.-Col. L. J. Blandford to be acting Colonel whilst employed as Deputy Director of Medical Services.

Lieut.-Col. T. F. Dewar to be acting Colonel whilst employed as Assistant Director of Medical Services.

Major G. C. Taylor, from Sanitary Service, to be Major.

2nd London Sanitary Company: Lieut. B. Chaikin to be Captain.

1st Lowland Field Ambulance: Major W. C. Murray to be a Deputy Assistant Director of Medical Services.

3rd West Lancashire Field Ambulance: Major A. A. W. Merrick, from Deputy Assistant Director of Medical Services, to be Major.

1st Home Counties Field Ambulance: Capt. C. H. Gregory, from Deputy Assistant Director of Medical Services, to be Captain.

Sanitary Service.—Lieut.-Col. L. J. Blandford to be Assistant Director of Medical Services, and to be temporary Colonel whilst so employed.

Lieut. Col. T. F. Dewar to be a Deputy Assistant Director of Medical Services.

Major G. C. Taylor to be a Deputy Assistant Director of Medical Services.

Attached to Units other than Medical Units.—Capt. A. S. M. Macgregor to be a Deputy Assistant Director of Medical Services.

TERRITORIAL FORCE RESERVE.

Major G. W. McIntosh, from Attached to Units other than Medical Units, to be Major.

Major (Brevet Lieut.-Col.) C. Rundle, from 1st Western General Hospital, to be Major.

Capt. W. M. Langdon, from the London Field Ambulance, to be Captain.

ROYAL AIR FORCE.

Medical Branch.—The undermentioned are granted temporary commissions as Captains:—T. E. Mulvany (late temporary Captain, R.A.M.C.) and R. J. Aherne (late temporary Captain, R.A.M.C.).

Dental Branch.—The undermentioned (temporary Captains, General List, Dental Surgeons) are granted temporary commissions as Captains: H. F. Barge, C. L. Colbran, C. J. Crocker, J. Speak, and T. F. Healey.

D. H. W. Williamson (temporary Lieutenant, General List, Dental Surgeon) is granted a temporary commission as Lieutenant.

THE Mental After-Care Association for Poor Persons Discharged Convalescent or Recovered from Institutions for the Insane, Church House, Westminster, earnestly appeals for further help to carry on and extend its work, which has largely increased owing to the many shell-shock and air-raid sufferers who have been among the applicants. The results of the work have been very satisfactory, and further particulars will be gladly given by the secretary.

Medical News.

UNIVERSITY OF OXFORD.—At examinations held recently the following candidates were successful:—

SECOND EXAMINATION FOR DEGREE OF BACHELOR OF MEDICINE.

Materia Medica and Pharmacology.—C. K. J. Hamilton, Lincoln; and M. H. MacKeith, Queen's.
Pathology.—H. P. Hodge, non-collegiate.
Forensic Medicine and Public Health.—Y. A. Brown, Exeter.
Medicine, Surgery, and Midwifery.—C. F. Krige, Hertford; A. E. Thomas, University; H. W. Toms, Jesus; and B. Tordoff, St. John's.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful:—

SECOND EXAMINATION FOR MEDICAL DEGREES.

Part II.—Frederick Bach, London Hosp.; Edward Townley Bailey, Middlesex Hosp.; *Cecil Stedman Cloake, Lond. Hosp.; Betty Dent, Lond. Sch. of Med. for Women; Archibald Glen Duncan, London Hosp.; Keridwen Valentine Edwards, Univ. Coll., Cardiff; Gertrude Evans, Lond. Sch. of Med. for Women; Olive Gwendolin Fisk, Girton Coll. and London Hosp.; Richard Kenrick Fou kes, King's Coll.; Nellie Gray, King's Coll. and Westminster Hosp.; Muriel Minnie Harris, Lond. Sch. of Med. for Women and King's Coll.; Hilda May Haythornthwaite and Marjorie Browning Hubert, Lond. Sch. of Med. for Women; Shankar Ramchandra Joglekar, Middlesex Hosp.; Dilys Menai Jones, Univ. Coll., Cardiff; Henry Charles Victor Joy, London Hosp.; Bessie Levin, Lond. Sch. of Med. for Women; William Alexander Low, St. Thomas's Hosp.; Ivan Bailey McCann and Alan McKenzie, Guy's Hosp.; Templar Edward Malins, Univ. Coll., Cardiff; Leslie Stuart Morgan, St. Bart.'s Hosp.; Ernest Rudolf Dudley Nagel, St. Thomas's Hosp.; Bertram Sydney Nissé, London Hosp.; Thomas Stanley North, St. Mary's Hosp.; Rupert John Parry, Univ. Coll., Cardiff; Frederick Alfred Pickworth, King's Coll.; Olive Gwendoline Potter, Girton Coll. and London Hosp.; Edward Horace Richards, Guy's Hosp.; Edith Margaret Ross-Johnson, Cambridge Univ.; Elizabeth Merriman Sanderson and Dorothy Mary Stewart, Lond. Sch. of Med. for Women; William Hedley Summerskill, Guy's Hosp.; Wenefride Thompson and Helen Caroline Tompson, Lond. Sch. of Med. for Women; Frederick H. Wickham Tozer, London Hosp.; and Edith Helen Trimmer, King's Coll. and St. George's Hosp.

* Distinguished in Physiology and in Pharmacology.

CENTRAL MIDWIVES BOARD FOR SCOTLAND.—At the meeting of the Central Midwives Board for Scotland held in the offices, 50, George-square, Edinburgh, Sir Halliday Croom in the chair, intimation was made of the appointment of Sir John Lorne MacLeod as representative of the Convention of Royal Burghs in place of the late Sir Robert Kirk Inches.—The following are the decisions in the cases of midwives heard before the Penal Board:—

No. 1240. For failing to send the proper form for medical assistance in a case of still-birth, &c. The midwife was cautioned strictly to observe the Rules of the Board, and the local supervising authority was instructed to report to the Board at the end of one month upon her conduct as a midwife and as to her fitness to take pulse and temperature.—No. 179. For failing to advise medical assistance in the case of a child suffering from serious skin eruptions and for other breaches of the Rules. The midwife was suspended from practice for one month, and the local supervising authority was instructed to report on her ability to take pulse and temperature before she resumed practice.—No. 1724. For failing to send for medical assistance in a case of ophthalmia neonatorum and for other breaches of the Rules. The secretary was instructed to remove the name from the Roll of Midwives and to cancel the certificate.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee, held on Dec. 10th, 30 cases were considered and £282 voted to 25 of the applicants. The following is a summary of some of the cases relieved:—

Widow, aged 82, and daughter, aged 42, of M.R.C.S. Eng. who practised at Camborne and died in 1892. The daughter has recently had an operation and is now unable to earn. Mother's income £79 from investments and an annuity. Owing to the high price of food unable to manage. Rent £32. Voted £10.—Widow, aged 65, of M.R.C.S. Eng. who practised at Brighton and died in 1898. Was left unprovided for with one daughter, now aged 38, who earns about £20 per annum as daily governess and lives at home. Applicant receives two small pensions amounting to £24. Rent £12. Applicant is now very ill. Voted £10.—Daughter, aged 12½, of L.S.A. Lond. who practised in North London and died in 1914. Mother also dead, and now in charge of an aunt, who applies for help towards clothes and holiday expenses. The aunt is a school mistress with £75 per annum, but owing to increased cost of living finds she cannot continue to keep her niece as she has done in the past. Voted £10.—Widow, aged 61, of M.R.C.S. Eng. who was in H.M. Prison Service and died in 1917. Has two daughters, now aged 37 and 34, working as temporary clerks. Husband left no means, and only income of applicant beyond help from her daughters is a small gift from another charity. Relieved once, £12. Voted £6.—Widow, aged 48, of L.R.C.P. Edin. who practised in Fife and died in 1913. Was left with six children, ages 27 to 10. She earns £30 by clerical work and receives £70 from children. Son on whom applicant mainly depends has been in hospital for three months. Relieved twice, £30. Voted £10 in two instalments.—Daughter, aged 40, of M.R.C.S. Eng. who practised at Streatham and died in 1914. Applicant's income is £20, and she lives with her mother, who also receives help from the Fund, and both are invalids. Relieved four times, £20. Voted £5.—Widow, aged 76, of M.R.C.S. Eng. who practised at Rye and died in 1891. Applicant receives £50 in dividends and lives in own house. A married daughter whose husband is in an

asylum lives with her. Applicant suffers from cataract in both eyes, and is too old to work. Relieved three times, £36. Voted £12 in 12 instalments.—Widow, aged 60, of L.F.P.S. Glasg. who practised at Heaton-on-Tyne and died in 1899. Left with six children, four of whom are married. One daughter, aged 27, at home to look after applicant, who is ill, and son, aged 19, who earns 28s. a week. Relieved 13 times, £142. Voted £12 in 12 instalments.—Daughter, aged 59, of M.R.C.S. Eng. who practised at Liverpool and died in 1893. Applicant was left without means, and is a chronic invalid and quite unable to work. An uncle pays her rent but cannot help further. Relieved 10 times, £114. Voted £12 in 12 instalments.—Daughter, aged 52, of L.R.C.S. Glasg. who practised in India and London and died in 1873. Applicant was left with about £20 per annum, and, being delicate, unable to undertake any regular employment. Relatives help occasionally. Relieved five times, £42. Voted £12 in 12 instalments.—Widow, aged 61, of L.S.A. Lond. who practised at Bournemouth and died in 1913. Was left entirely without means. Receives a pension of £26 from another society and tries to supplement this by taking in lodgers, but has not been successful. Relieved four times, £48. Voted £12 in 12 instalments.—Widow, aged 51, of M.R.C.S. Eng. who practised at Westminster and died in 1911. Applicant was left entirely unprovided for and has endeavoured to earn a living by teaching music, but owing to the war she has not many pupils. Relieved £5 some years ago. Voted £10 in two instalments.

Subscriptions may be sent to the acting honorary treasurer, Dr. Samuel West, at 11, Chandos-street, Cavendish-square, London, W. 1.

THE death is announced, on Dec. 13th, at the age of 66, of Dr. George Ogilvie, late senior physician to the French Hospital and to the Hospital for Epilepsy and Paralysis, Maida Vale.

A NURSING HOME TRAGEDY.—A Hove jury on Dec. 12th having returned a verdict of "Death from misadventure," the coroner recorded that Mary Jane Gray died from a fracture of the skull, caused by falling downstairs when struggling to prevent a male patient of unsound mind and insufficiently clad escaping from the house at night. Mrs. Gray was the matron of a nursing home. On Nov. 30th a patient entered with nervous breakdown. He had been a sheep farmer in New Zealand and only married on Nov. 14th. His condition developed into insanity in a very short time, and on Dec. 5th, five days after his admission, he overpowered those in the house, and in the struggle on the stairs the patient and Mrs. Gray fell to the bottom, Mrs. Gray dying from the injuries received. The patient escaped from the house, but was secured and removed to the county asylum. The jury added a rider to their verdict expressing the view that the care of male patients suffering from nervous maladies was not fit work for women alone without assistance, and that it should be enacted that at least one male attendant should be on duty in every nursing home. The coroner agreed to lay the matter before the proper authorities. On behalf of the family the deepest sympathy was expressed to the relatives of the deceased lady.

Communications, Letters, &c., to the Editor have been received from—

J.—Capt. W. H. Johnston, R.A.M.C.; Dr. G. Jessel, Wigan.

K.—Mr. W. H. Kesteven, Kingston Hill; Sapper L. Kelly, R.E.; Dr. F. H. Kelly, Hurstpierpoint.

L.—Major J. R. Lee, R.A.M.C.; Lieut. S. G. Lenzner, M.C., U.S.A.; Mr. E. M. Little, Lond.; Mrs. B. H. Leigh, Lond.; Dr. G. C. Low, Lond.; Local Government Board, Lond.

M.—Capt. R. J. Matthews; Medical Supply Association, Lond.; Dr. N. Macleod, Shanghai; Medical Research Committee, Lond.; Metropolitan Hospital Sunday Fund, Lond., Sec. of.

N.—Mr. W. G. Nash, Bedford

O.—Rev. E. G. O'Donoghue, Lond.

P.—Capt. E. W. Pineo, R.A.M.C.; Capt. E. Prideaux, R.A.M.C.; Panel Committee for the County of London; Miss K. Pilkington, Lond.; Major M. G. Pearson, S.A.M.C.; Sir R. D. Powell, Bart., K.C.V.O.; Dr. D. Pennington, Lond.; Major J. Parkinson, R.A.M.C.; Dr. J. Phillips, Bradford.

R.—Capt. H. Robinson, R.A.M.C.; Royal Dental Hospital of London, Sec. of.

S.—Sir G. H. Savage, Lond.; Mr. A. Scott, Lond.; Capt. H. G. F. Spurrell, R.A.M.C.; Dr. E. I. Spriggs, Banff; Surgical Instrument Manufacturers Association, Lond., Hon. Sec. of.

U.—United States Government Committee on Public Information, Lond.

V.—Dr. C. W. Vining, Leeds; Dr. F. Villy, Keighley.

W.—Dr. E. H. Worth, Lond.; Dr. W. H. White, Lond.; Dr. H. Woods, Lond.; Dr. J. A. Wilson, Warrington; Dr. G. D. H. Wallace, Rochester.

Communications relating to editorial business should be addressed exclusively to The Editor of THE LANCET, 423, Strand, London, W.C. 2

THE LANCET, VOL. II., 1918: THE INDEX.

THE Index and Title-page to the volume of THE LANCET to be completed with the issue of Dec. 28th is in preparation. Owing to the continued shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a *post-card* (which is more convenient for filing purposes than a letter) to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

Appointments.

ALBAN, EDGAR, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., Barrister-at-Law (Lincoln's Inn), has been appointed Deputy Coroner in the South-Eastern District to Dr. H. R. Oswald, one of H.M. Coroners for the County of London.

MACCARTHY, D., M.B., Certifying Surgeon under the Factory and Workshop Acts for the Ballyfeard District of the county of Cork.

Vacancies.

For further information refer to the advertisement columns.

Alton, Hants, Lord Mayor Treloar Cripples' Hosp.—Asst. Res. M.O. £200.
Barnstaple, North Devon Infirmary.—H.S. £150.
Barrow-in-Furness, North Lonsdale Hospital.—Second H.S. £250.
Bedford County Hospital.—H.S. or Clin. Asst.
Bootle Hospital, near Liverpool.—Jun. H.S. £170.
Brighton, Royal Sussex County Hospital.—Asst. Path. £200.
Cardiff, King Edward VII.'s Hospital.—H.S. £200. Also Student Dresser. 52 gs.
Dudley, Guest Hospital.—Hon. Surg. Staff.
Evelina Hospital for Children, Southwark, S.E.—H.P. and H.S. £160.
Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—1st and 2nd H.S.'s. £175 and £150 respectively.
Hospital in Serbia.—S.
Oxford, Radcliffe Infirmary and County Hospital.—H.P. £200.
Plymouth, South Devon and East Cornwall Hospital.—M.O. £350.
Putney Hospital, Lower Common, S.W.—Res. M.O. £150.
Salisbury General Infirmary.—Asst. H.S. £150.
Sheffield City Education Committee.—Asst. Sch. M.O. £400.
Southampton Free Eye Hospital.—Asst. Oph. Surg. £100.
Whitehaven and West Cumberland Infirmary.—Res. H.S. £150 to £180.

AN appointment is vacant for a Medical Referee under the Workmen's Compensation Act, 1906, for the Dartford and Gravesend County Courts. Applications should be addressed to the Private Secretary, Home Office, not later than Jan. 6th, 1919.

Births, Marriages, and Deaths.

BIRTHS

FOSTER.—On Dec. 11th, at St. Loyes, Exeter, Anita, wife of Major Raymond L. V. Foster, R.A.M.C., of a son.

HALL.—On Dec. 15th, Margaret, the wife of Major G. Hall, C.M.G., R.A.M.C. (T.), Ellison-place, Newcastle-on-Tyne, of a daughter.

KERR.—On Dec. 10th, at Clairmont-gardens, Glasgow, the wife of Professor Munro Kerr, M.D., of a daughter.

SETH-SMITH.—On Dec. 14th, at Tower House, Bildeston, Suffolk, the wife of D. N. Seth-Smith, M.R.C.S., L.R.C.P., of a daughter.

SHARMAN.—On Dec. 12th, at Avenue-mansions, Hampstead, the wife of Henry Sharman, M.D., of a daughter.

MARRIAGES

BEAUMONT—HOUSTON.—On Dec. 14th, at the Parish Church, Pinner, Captain Vincent Beaumont, R.A.M.C., to Margaret Elma (Peggie), only daughter of the late T. J. Houston, J.P., Co. Wexford, Ireland.

KELSALL—ELDERTON.—On Dec. 13th, at St. Leonard's Church, Streatham, Major (acting Lieutenant-Colonel) Robert Kelsall, D.S.O., I.M.S., to Margaret Florence, third daughter of the late W. A. Elderton and Mrs. Elderton, Mount Ephraim-road, Streatham.

SHEPHERD—SULLY.—On Dec. 12th, at St. Andrew's Church, Cardiff, Charles Woolley Shepherd, M.B., B.S., of St. Andrew's-crescent, Cardiff, to Enid Mary, elder daughter of George Ernest and Mary Sully, of Park-place, Cardiff.

DEATHS

COTTERILL.—On Dec. 2nd, at No. 50 Casualty Clearing Station, France, of pneumonia, Captain Denis Cotterill, F.R.C.S. Edin., R.A.M.C.

FORD.—On Dec. 13th, at Sea View, Isle of Wight, after a long illness, Arthur Vernon Ford, Major, R.A.M.C. (T.).

OGILVIE.—On Dec. 13th, at Welbeck-street, after a short illness, George Ogilvie, F.R.C.P., Chevalier de la Légion d'Honneur, aged 66.

WINTER.—On Dec. 3rd, in British Honduras, of pneumonia, William Cecil Pollard Winter, M.R.C.S., L.R.C.P., Colonial Medical Service.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL.—During next week clinics will be held each week-day (except on Christmas Day and Boxing Day) at 2 P.M., Friday and Saturday also at 10 A.M.

Notes, Short Comments, and Answers to Correspondents.

THE ORGANISATION WORK OF CHILD WELFARE.

AT the Royal Institute of Public Health on Dec. 11th, Sir John Kirk presiding, Dr. Eric Pritchard spoke on the Organisation and Administration of Child-Welfare Centres. Comparing the present organisation with that of four years ago, an astonishing progress had been made. At the onset of the war no immediate prospect existed of grants-in-aid for child-welfare work. Now these grants were a matter of past history. In the face of official organisation there was a danger of doing scant justice to the army of voluntary workers who had done the spade-work for the past 10 or 15 years. Voluntary workers were not getting all the credit they deserved. It was the National Society for the Prevention of Infant Mortality and other voluntary associations whose propaganda work had rendered possible the present advances in official organised work. Without the voluntary worker the whole child-welfare movement would tend to become officialised. The recent Maternity and Child-Welfare Act sanctioned the coöption of outside workers on the municipal committees up to one-third of their total number, the presence of two women being obligatory. In the past the valuable suggestions of coöpted workers had been too often thrown out time after time by the plenary council. While he would like to see the whole of the maternity and child-welfare work taken over by the public health authority he would leave to the committees very considerable freedom in the control of the work and would encourage the assistance of volunteers prepared to help in any part of the district. The details of organisation could hardly be straightened out until a Ministry of Health was formed. When this had been done one of the first essentials would be to obtain a survey of the physical condition of the inhabitants of the British Isles, each person receiving a health card to be filled in from birth till death. An attempt had already been made to pass on records from welfare centres to school authorities, but only on a small scale. Dr. Pritchard favoured the scheme propounded by Dr. Gerstenberger in 1913 of a central child-welfare institute in direct *rapport* with outlying prophylactic centres, and with various special departments to which children could be brought for inspection. Attached to the centre would be a milk depôt and one or more institutions to which children could be sent for treatment, the whole country being divided up into areas of suitable size for the purpose. Dental clinics had already taken a useful place and their permanent value would be greatly increased if the attending dentist was a teacher able and willing to instruct the health visitors and voluntary workers present. The value of observation wards for sick children is, in Dr. Pritchard's view, educational rather than curative. Only a relatively small number of the cases attending at welfare centres were not amenable to home treatment by mothers acting on the advice given at the centres. The wards should be in relation to some hospital, so that serious cases could be passed on for treatment. Nurses and probationers were apt to look upon the children in such wards from a wrong point of view, that of disease instead of health. In his experience no more than four babies should occupy the same room. One was the ideal number; beyond this number all the babies were liable to suffer from the infective flora introduced by the others. After touching on the keeping of records and the ideal qualifications of health visitors, Dr. Pritchard went on to speak of the equipment desirable for the medical officer who supervised the work. The Local Government Board did not recommend a rota of doctors, a method which resulted in confusing the poor women who attended the centres by the conflicting advice given to them. The appointment to a health centre of a children's specialist from a hospital was no more successful, for he was apt to take a pathological rather than a physiological point of view. Nor was the general practitioner always to be desired, unless he took a special interest in children. The best practice was, he thought, to appoint a recently qualified woman doctor who had served an apprenticeship in a children's hospital and in the medical inspection of school children.

UNAUTHORISED.

THE Home Secretary has given notice that he has directed that George Frederick Handel Bartlett, chemist and druggist, of 38, Battersea Park-road, 236, Battersea Park-road, and 143, High-street, Battersea, who on Oct. 17th last was convicted of offences under Defence of the Realm Regulation 40 B, shall cease to be an authorised person for the purposes of that Regulation, which regulates dealings in cocaine and opium. The effect of this order is that Bartlett may no longer purchase or be in possession of opium or cocaine, and any person supplying him with these drugs will be committing an offence against the Regulation.

HOSPITAL ECONOMIES.

Lord Knutsford has given an interesting account of fuel and light saving effected at the London Hospital. As an exercise of thoughtfulness and reorganisation in large institutions the economy campaign at the London is notable and well worthy of imitation.

"It should be distinctly understood," said Lord Knutsford, "that economy has been effected without any lowering of the standard of treatment. For instance, there has been, and there can be, no question of reducing the large amount of electric current which is essential for X ray treatment, Tyrnauer baths, and Finsen lamp treatment. But as the result of organised effort, in which the entire staff are coöperating loyally, we have cut down light and fuel consumption in many other directions. The electricity consumption has been reduced from 170,000 units to 132,000 units. This includes the lighting of out-patient departments, theatres, and wards."

The following are some of the directions in which economy has been exercised:—

All baths have been marked with "high-water marks," above which the water is not to run.

The hot-water central heating system has been improved and rendered more efficient. A new boiler has been installed in the laundry, obviating the loss which was entailed by leading steam through 300 yards of piping.

Unnecessary bedside lights have been removed. Many electric lights have been cut out, some wholly, and others replaced by lamps of low candle-power.

All cooking is done by gas.

Clinical photography has been discontinued to economise current.

Sterilisers are only used at certain hours of the day.

Separate meters have been installed in every department and are read weekly. By this means extravagance is immediately traceable, and should such occur a notification is sent to the head of the department requiring him to cut down consumption, and the meter is examined to see that the instruction is carried out.

An economy leaflet has been issued to each sister and nurse, and to each outgoing patient.

The dental school has been partially closed.

THE "ABDULLA" ALMANAC, 1919.

Messrs. Abdulla and Co., of 173, New Bond-street, London, W.1, have again brought out an attractive almanac containing reproductions of pictures by well-known artists, the larger proportion in colour. The latter are particularly well executed, and include examples of the work of Charles E. Brock and Lionel Edwards. 20,000 copies are offered for sale at 1*s.* 4*d.* post free, of which 1*s.* a copy goes to the funds of the British Red Cross Society.

THE TREATMENT OF SCURVY.

To the Editor of THE LANCET.

SIR,—James Cooke, in his Marrow of Surgery to which is added the Marrow of Physick, published in 1676, gives the following prescription for scurvy "which hath been oft proved excellent":—

"Take of the biggest leaves of scurvy-grass N. 12, raisins of the sun stoned N. 20 shavings of horse-radish roots 3iss. Put them in a quart bottle of beer or ale; after two days drink it for ordinary drink. You may make as many bottles as you please, drinking it for a long time."

Scurvy-grass, it may be mentioned, is a biennial herb (*Cochlearia officinalis*) of the mustard family, highly prized by Arctic explorers for food and as a remedy for scurvy. In the light of recent observations it would be interesting to apportion the relative efficacy of the various constituents of this drink against the disease. At any rate, it is to be noted that the vehicle is beer or ale, presumably home-brewed.

I am, Sir, yours faithfully,

Lowestoft, Dec. 15th, 1918. H. MUIR EVANS, M.D.

PLAGUE DISPENSARIES.

TRAVELLING dispensaries are a feature of Indian administration, and a report on plague administration shows that by February of this year these mobile dispensaries were increased to 110 to meet the severe plague epidemic. The additional dispensaries (23) were to close at the end of May, but were required for relapsing fever work. Compounders were specially trained by civil surgeons in inoculation work and in the treatment of plague and relapsing fever, and were put in charge of the dispensaries when a sub-assistant surgeon was not available. These trained medical assistants are working quite satisfactorily. It is due to the formation of these additional travelling dispensaries that it has been possible to cope, to some considerable extent at least, with the outbreak of relapsing fever in the western districts and with a severe epidemic of cholera in the eastern districts. Travelling dispensaries are coming to be recognised as an established institution in some provinces, and are enjoying ever increasing popularity. There has been an increase of 41,493 in the number of patients treated by them during the year, and 929,279 patients were treated (new and old cases) against 887,786 last year. 18,290 operations were performed by the travelling dispensaries, 694 of which were major operations, including 302 cataract operations, which were mostly done by civil surgeons. The travelling dispensaries do useful educational work by the distribution of pamphlets relating to plague, malaria, relapsing fever, cholera, small-pox, and tuberculosis.

Some Observations ON THE BACTERIOLOGY AND PATHOLOGY OF "INFLUENZA."

Delivered at the Royal Society of Medicine on Nov. 13th, 1918,

BY HAROLD E. WHITTINGHAM, M.B., CH.B. GLASG.,

CAPTAIN, R.A.M.C. (T.C.), ATTACHED R.A.F.; BACTERIOLOGIST, R.A.F. CENTRAL HOSPITAL, HAMPSTEAD;

AND

CARRIE SIMS, M.B., CH.B., BIRM.,

R.A.M.C. (ATTD.); BACTERIOLOGIST, MILITARY HOSPITAL, HAMPSTEAD.

THE following investigations were undertaken to ascertain whether the present October "influenzal" epidemic and the July "Spanish plague" were due to one and the same micro-organism or group of organisms.

That the causal organisms were not the same in both cases was suggested by the distinct difference in the signs and symptoms, the physical signs of pulmonary involvement being marked in the present disease, but only transient or absent in the July epidemic. A dry hacking cough is an early symptom; in fact, often the only one of which the patient complains. Moreover, in July the febrile period frequently lasted three, and more rarely six, days; in the present disease the febrile period is longer—seven to fourteen days—and the temperature higher throughout. In short, pharyngitis and laryngitis, with marked nervous prostration, distinguished the earlier epidemic; bronchitis and broncho-pneumonia, with septicæmia, the plague now with us.

The varying reports that have been published concerning influenza in the last four months must cause the general public to remark, "Doctors always differ!" but the professional mind wonders if all observers have been studying one and the same disease. There is a distinct tendency when an epidemic disease is raging to assign all maladies to the one common origin. Thus many pyrexias of sudden onset, such as acute tonsillitis, lobar pneumonia, cerebro-spinal fever, are labelled "influenza." In the following notes we wish to emphasise the fact that we are dealing with a "compound" disease.

Over a hundred cases were examined as regards the micro-organisms present in the posterior nasal swabs and sputa. The urine of these cases was also examined on several occasions. As blood cultures were performed on only the first 50 of the cases admitted to the two hospitals in which we worked, we have based all our figures on these 50 cases. Taking each case as admitted, whether mild or severe, gives as fair a picture as possible of the pathological findings of the disease.

Fortunately the cases dealt with in this paper are directly comparable to those reported on in July.[1] In both epidemics the patients were Royal Air Force officers and cadets from the same district and living under similar conditions.

BLOOD CULTURES.

Blood cultures were performed on 50 cases.

In each case 10 c.cm. of blood was added to 100 c.cm. of citrated broth and incubated at 37° C. for eight days. Several loopfuls of each broth culture were sown daily on blood agar and slides made in case micro-organisms were present which would not subculture.

Positive results were obtained in 7 of the cases (i.e., 14 per cent.); of these, 5 proved to be streptococcus, 1 pneumococcus, and 1 resembled the *Diplococcus mucosus* of Stephan.[2]

The streptococci varied as regards the first day on which sub-cultures could be obtained from the broth cultures. Four days was the longest period; in one case the growth of streptococci in the original broth culture was very abundant in 24 hours. The pneumococcus was subcultured out after two days in broth, the *Diplococcus mucosus* after three days.

Three of the streptococci isolated hæmolysed distinctly and two slightly. Only one of these grew in long chains in broth, the rest being short and arranged more or less in diplococcal formations. Growth on agar at 20° C. was slow and poor, at 37° C. moderate. All grew well on blood agar, giving typical colonies, in two the viridans type. Inulin was not fermented. Capsule formation absent. Acid and clot in milk on the second to third day. Only two of these streptococci were subjected to animal experimentation. Both organisms proved to be non-pathogenic to young rabbits when inoculated subcutaneously.

The pneumococcus was quite characteristic—capsule formation was present and inulin fermented. A young rabbit inoculated subcutaneously in the flank died in 30 hours. Pneumococci were found abundant in the heart's blood; there was marked congestion of trachea and lungs, petechial hæmorrhages of pleura and peritoneum, especially the latter, and fluid pus in the peritoneal sac.

The *diplococcus mucosus* when first isolated appeared as a Gram-negative diplococcus (each coccus measuring about 0·7 to 1 μ in diameter), very similar to the meningococcal group, except that there was a distinct capsule. When incubated at 37° C. it grew as small, rounded, semi-transparent, pin-head colonies on blood agar and even on agar in 24 hours; at 20° C. it grew visibly in 40 hours. The colonies became somewhat granular after 48 hours.

Smears made from the second subculture onwards showed the organism to be very pleomorphic; in places it appeared as rounded, in others as oval diplococci, while at times small bacillary forms were seen. The staining with Gram's was variable in the same smear, some of the cocci being distinctly positive and others negative. The bacillary forms were Gram negative.

That these were not influenza bacilli is evident from their growth on ordinary agar, and also from the fact that they stained readily with 1 in 10 fuchsin in ten to twenty seconds. A contamination was suspected, but these small bacillary and variable Gram staining forms were found when individual plate colonies were examined.

In broth there was distinct general turbidity in 24 hours; this cleared somewhat on the third day, and a fine powdery deposit covered the bottom of the tube. Acid was produced in glucose, saccharose, maltose, lævulose, and galactose, but not in lactose, mannite, dulcite, or inulin. Litmus milk on the second day showed slight acid reaction and slight basal clot formation, which became more marked on the following day. There was only slight hæmolysis of blood media.

Experimental inoculation, intravenously and subcutaneously, into young rabbits proved the organism to be non-pathogenic to these animals. It should be noted that the patient died from whom this organism was isolated. Unfortunately a post-mortem examination could not be obtained.

Note.—At one period of these investigations blood from some of the cases which gave a negative result on culture was used to make blood agar. The growth of some of our stock cultures was poor on this media, so two series of blood agar tubes were put up, one series being made from the blood of apparently normal individuals, the other from the blood of influenza patients. *B. influenzæ*, pneumococcus, streptococcus, and meningococcus isolated from cases under investigation, were implanted into tubes of the first and second series respectively. The result, read at the end of 48 hours, was a good growth of all the organisms in the normal blood series, while in the influenza blood series practically no growth of the *B. influenzæ* occurred and only comparatively feeble growths of the pneumococcus, streptococcus, and meningococcus. This result, at least as regards the *B. influenzæ*, was to be expected. The experiment is mentioned to emphasise the fallacy of using blood from "influenza" patients to make up media for the isolation of the micro-organisms in such an epidemic.

Of the 50 cases death occurred in 7, 5 of which gave positive blood cultures during life (streptococcus in 4, *D. mucosus* in 1)—i.e., 71 per cent. of the cases in which micro-organisms were isolated from the blood died. Amongst the patients giving a negative blood culture 2 died—i.e., 4·6 per cent. Of these, one was a case of cerebro-spinal meningitis; the other of purulent bronchitis with pleurisy and peritonitis. From the latter case streptococcus was isolated from the heart's blood at the post-mortem; so probably if blood cultures had been made on this patient late in the disease a positive result would have been obtained.

The day of disease on which the various blood cultures were made and the results of culture are shown in Table I. A glance at these figures would suggest that if all the blood cultures had been taken on the sixth or seventh day of disease many more positive results would have been obtained. As it is, there are not enough figures to go by, but, in considering the table, one must bear in mind that the bloods cultured on the sixth and seventh days were from those patients who were progressing badly and already in a markedly toxic condition.

In the July epidemic[1] blood cultures were repeatedly negative, except on two occasions when Gram-negative diplococci were found, which would not subculture.

TABLE I.—*Results of Blood Cultures in 50 Cases.*

Day of disease.	1	2	3	4	5	6	7	Total.
Cases cultured ...	10	14	16	2	5	1	2	50
,, positive ...	—	1	2	—	1	1	2	7
Per cent. ,, ...	0	7	12·5	0	20	100	100	14

We have repeatedly observed, both in this and the previous epidemic, that after the withdrawal of 10–20 c.cm. of blood early in the disease, for culturing purposes, there is a distinct fall in the temperature. We mention this as a point worthy of note for clinicians.

THROAT SWABS AND SPUTUM.

Posterior nasal swabs were examined from 50 cases.

In each case direct smears and plate cultures were made. In those cases where there was expectoration the sputum was examined—23 out

of the 50 cases. The sputum to be cultured was first well washed in sterile salt solution. The plates were examined at the end of 24 and 48 hours' incubation at 37° C.

TABLE II.—*Bacteriology of Sputa and Throat Swabs.*

Direct smears.	Cases.	*Cultures.*	Cases.
Diplococci—		*M. catarrhalis*	36
Gram —	49	Pneumococcus	33

Streptococcus	82 ,,	76 ,,	80 ,,	Meningococcus	—	8 ,,	8 ,,
B. influenzæ	54 ,,	38 ,,	46 ,,	Staphylococcus	44 ,,	52 ,,	54 ,,

(1) Sputum (23 cases). (2) Throat swabs (50 cases). (3) Combined sputum and throat swabs.
Only the chief micro-organisms are shown.

In order to gain some idea of the micro-organisms present in all cases the throat swabs and sputum results had to be combined, as sputum could only be obtained from some of the patients. This combination varied only slightly from the two separate returns. (Table III.)

The examination showed a very mixed and fairly constant flora in all cases. The chief micro-organisms present were streptococcus in 80, pneumococcus in 66, *M. catarrhalis* in 72, staphylococcus in 54, *B. influenzæ* in 46, *B. septus* in 20, pneumobacillus in 16, and meningococcus in 8 per cent. of the cases. The percentages were taken from the cultures and not from the direct smears. (Table II.)

These micro-organisms merit a more detailed description. We were unable in a routine laboratory to put the various organisms through a full series of tests, but had to confine ourselves to the standards stated below.

Streptococcus.—The streptococci present were for the most part diplo-streptococci in short or long chains. They were usually Gram-positive, although at times some units of the chains were Gram-negative. Growth on agar was slow at room temperature. Acid was produced in glucose, lactose, saccharose, and maltose. Mannite, dulcite, and inulin were unchanged. Litmus milk was rendered slightly acid with the formation of clot in most cases. The hæmolytic action of these organisms varied. Briefly, the *longus* type hæmolysed strongly, whereas the *brevis* type produced little or no hæmolysis, and the colonies had a greenish colour. Some of the *brevis* type caused distinct hæmolysis. We therefore divided the *streptococci* into *hæmolyticus* and *non-hæmolyticus*, depending on the degree of hæmolysis rather than on the actual length of the coccal chains. *Streptococcus hæmolyticus* was present in 46 per cent., *non-hæmolyticus* in 34 per cent. of the cases; from the remaining 20 per cent. streptococci could not be obtained. Streptococci were the predominant organisms in 30 per cent. of the cases.

Pneumococcus.—Difficulty was experienced in classifying certain of the Gram-positive diplococci found. Some were distinctly lanceolate in direct smears, while others were rounded. In cultures the varieties of form and chain formation rendered the task more difficult. As in the case of the streptococci, the Gram staining was a little variable at times. In some instances inulin was fermented; in others acid production was absent in this sugar. Hæmolysis was even produced by some of these pneumococci. The presence of a capsule was the deciding element in these cases. Probably some of the so-called pneumococci were really streptococci or the *Diplococcus epidemicus* of Bernhardt,[3] but in the absence of animal inoculation in all cases the returns had to be made as stated above. Pneumococci predominated in 28 per cent. of the cases.

Micrococcus catarrhalis.—Under this head are grouped all the Gram-negative diplococci, most of which grew on agar at 20° C., but did not produce any acid formation in glucose, lactose, saccharose, mannite, maltose, or inulin. In 34 per cent. of the cases *M. catarrhalis* was the predominant germ. These organisms were very similar to those isolated so frequently in the previous epidemic.[1]

B. influenzæ.—Minute bacilli or cocco-bacilli which failed to grow on ordinary agar at 37° C. and would not ferment either glucose, lactose, saccharose, mannite, maltose, or dulcite. These Pfeiffer-like bacilli were found in many of the cases, usually in small numbers, but in one case it was the predominant micro-organism.

Staphylococcus.—This was the predominant organism in 8 per cent. of the cases. Both varieties, *aureus* and *albus*, were present, most frequently the former. (See Table II.)

Meningococcus.—From the posterior nares of four cases meningococci were isolated. Two of these cases developed typical cerebro-spinal fever, two failed to show meningeal signs and were apparently carriers.

POST-MORTEM EXAMINATIONS.

Of the fifty cases dealt with in this paper there were 7 deaths, giving a case mortality of 14 per cent. The average age of the patients treated was 25, that of those who died 23, the youngest and oldest of this series being 19 and 29 years of age respectively. The day of disease on which death took place varied from the fifth to the fourteenth

Post-mortem examinations were performed on only five cases. Broadly speaking, the pathological findings were more marked in those who died later in the course of the disease. Beyond this we cannot generalise from so small a number of cases. A summary of the main points is given, as it may be of value for statistical purposes.

Synopsis of Post-Mortem Findings.

Case 12.—Trachea: Acute congestion. Small white fibrinous patches. Bronchi: Acute congestion. Submucosal hæmorrhages. Lungs: Both congested and œdematous. Pleuræ: Blood-stained exudate (left, 30 c.cm., right, 50 c.cm.). Adhesions at base, recent in left. Petechial hæmorrhages. Pericardium: Normal. Heart: Slight dilatation right heart, pallor cardiac muscle. Sub-endocardial injection. Aorta: Marked sub-intimal injection. Bronchial lymph glands: Normal. Peritoneum: Few petechial hæmorrhages. Stomach and intestines: Submucosal hæmorrhages. Liver: Slightly fatty. Spleen: Slightly enlarged, congested, pulpy. Kidneys: Congested. Brain and meninges: Congested. Cerebro-spinal fluid: Normal.

B. influenzæ isolated from bronchi and lungs, pneumococcus from lung; streptococcus from lung and bronchi, spleen, pleuritic fluid.

Case 39.—Trachea: Acute congestion; small white fibrinous patches. Bronchi: Acute congestion. Lungs: Congested and œdematous. Pleuræ: Recent adhesions left apex and base. Slight petechial hæmorrhages (both). Pericardium: Normal. Heart: Dilatation right heart. Muscle pale. Aorta: Normal. Bronchial lymph glands: Normal. Peritoneum: Petechial hæmorrhages distinct. Stomach and intestines: Normal. Liver: Slightly fatty. Spleen: Slightly enlarged, congested, pulpy. Kidneys: Congested. Brain and meninges: Normal. C.S. fluid: Normal.

Pneumococcus isolated from lungs and bronchi; streptococcus from lungs and bronchi; *Staphylococcus aureus* from lungs and bronchi; pneumobacillus from lung.

Case 19.—Trachea and bronchi: Acute congestion. Lungs: Left—Lobes adherent. Lung collapsed. Purulent bronchitis lower lobe. Right—Basal congestion. Pleuræ: Left—500 c.cm. turbid fluid (exudate). Fibrinous exudate over lower part lung and diaphragm. Right—A few petechial hæmorrhages. Pericardium: Normal. Heart: Slight dilatation right heart. Pallor of cardiac muscle. Sub-endocardial injection. Aorta: Normal. Bronchial lymph glands: Enlarged and congested. Peritoneum: Fibro-purulent peritonitis. Petechial hæmorrhage. Stomach and intestines: Fibrinous adhesions. Liver: Slightly fatty. Spleen: Slightly enlarged, congested, pulpy. Kidneys: Toxic nephritis. Brain and meninges: Normal. C.S. fluid: Normal.

Streptococcus isolated from lungs, heart's blood, spleen, peritoneal fluid, pleuritic fluid.

Case 5.—Trachea: Acute congestion. Small, white, fibrinous patches. Bronchi: Acute congestion. Coated with fibrinous lymph. Filled with pus. Lungs: Left—Lobes adherent. Lung collapsed. Purulent broncho-pneumonia. Right—Lobes slightly adherent. Marked congestion. Pleuræ: Empyema (left). Petechial hæmorrhages (both). Pericardium: Sero-fibrinous pericarditis. Petechial hæmorrhages. Heart: Dilatation right heart. Pallor of cardiac muscle. Sub-endocardial injection marked. Aorta: Marked sub-intimal injection. Bronchial lymph glands: Enlarged and congested. Peritoneum: Petechial hæmorrhages, especially over liver and diaphragm. Stomach and intestines: Submucosal hæmorrhages. Liver: Slightly fatty. Spleen: Slightly enlarged, congested, pulpy. Kidneys: Toxic nephritis. Brain and meninges: Congested. C.S. fluid: Normal.

Pneumococcus isolated from lungs, bronchi, pericardial sac, pleuritic fluid; streptococcus from lung, bronchi, heart's blood, pleuritic fluid; *Staphylococcus aureus* from lungs and bronchi, pleuritic fluid; pneumobacillus from lung.

Case 30.—Trachea: Acute congestion. Small white fibrinous patches. Bronchi: Acute congestion. Fibrinous patches. Submucosal hæmorrhages. Lungs: Lobar pneumonia of left lower lobe, and of right lower and mid lobes. Pleuræ: Blood-stained fluid 400 c.cm. left, 200 c.cm. right. Recent adhesions left base. Adhesions posteriorly right pleura. Petechial hæmorrhages (both). Pericardium: Normal. Heart: Dilatation right heart. Pallor cardiac muscle, slight sub-endocardial injection. Aorta: Marked sub-intimal injection. Bronchial lymph glands: Enlarged and congested. Peritoneum: Petechial hæmorrhages. Stomach and intestines: Normal. Liver: Slightly fatty. Spleen: Normal. Kidneys: Cloudy swelling and fatty changes. Brain and meninges: Normal. C. S fluid: Normal.

Pneumococcus isolated from lungs, pleuritic fluid; streptococcus from lungs and bronchi, pleuritic fluid.

Summary of Post-Mortem Findings.

Pharynx and larynx.—Showed only slight congestion.

Trachea.—In the five cases there was marked acute congestion of the mucosa; thin, whitish, fibrinous patches here and there. These changes were more marked in the lower part. In two of the cases greenish-yellow pus filled the lumen of the tube.

Thorax.—Bronchi were markedly congested in all cases, the mucosa being very bright red in colour. Pus filled them in two cases as mentioned under trachea.

Lungs.—In the two cases which died on the fifth day there were only marked congestion and œdema of both lungs. One case presented the picture of purulent bronchitis; one of purulent broncho-pneumonia. In both cases there was collapse of the left lung. In the remaining case there was double lobar pneumonia (early grey hepatisation).

Pleuræ.—In all cases there were numerous small petechial hæmorrhages, especially under the visceral layer at the bases of the lungs. A fibrinous exudate loosely bound the bases of the lungs of one case to the parietal wall, while in two other cases both pleural sacs contained about a pint of blood-stained inflammatory exudate. In two further cases unilateral empyema was present—in both instances the left pleural sac was involved. Several pints of sero-pus almost filled the sac in one of these cases.

Pericardium.—Sero-fibrinous pericarditis was present in one of the cases with empyema. Petechial hæmorrhages studded the epicardium in this case. Fibrinous patches covered the surface of the right ventricle, especially towards its base. In the other four cases the pericardium was normal.

Heart.—In all cases there was more or less dilatation of the right heart, ante-mortem clot in right auricle and ventricle, and pallor of the cardiac muscle. In all except one case there was marked injection of the endocardium, especially in the valvular regions extending into the pulmonary arteries and aortic arch (aortitis).

Bronchial lymph glands were distinctly enlarged, soft, and congested in three of the cases.

Abdomen.—*Peritoneum.*—Fibro-purulent peritonitis was found in one case and petechial hæmorrhages in all, best marked over the liver, especially the diaphragmatic surface.

Liver.—Early fatty changes throughout.

Spleen.—Somewhat enlarged, congested, soft and pulpy, except in one case where there was no change.

Kidneys.—In one, slight fatty changes; two showed marked congestion, and two distinct toxic nephritis.

Stomach and intestines.—Submucosal hæmorrhages in two cases.

Brain.—Distinct congestion of meninges and grey matter of the cortex in two cases. Ventricular fluid normal in all.

The bacteriological examination of materials taken at the post-mortem showed: *B. influenzæ* in the bronchial discharges and lungs in one case only. Pneumococci were present in the bronchial discharges, lung smears, and pleuritic fluid of these cases; in every instance accompanied by streptococci, and in two cases by *Staphylococcus aureus*. On one occasion pneumococci were isolated from the pericardial sac.

Streptococci were present in the bronchi and lungs of all five cases, in the pleuritic fluid of four, heart's blood and spleen of three, and peritoneal fluid of one. The cocci conformed to the *hæmolyticus* type in all except one case. Pneumobacilli were isolated from the lungs of two cases. *Staphylococcus aureus* in the bronchi and lungs of two cases.

THE URINE.

The urines from 50 cases were subjected to a thorough routine examination. The outstanding features were the presence of albumin and renal casts in many, acetone and excess of urates in some, especially at the height of fever in the pneumonic cases. The acetone disappeared with the fever.

As in the July epidemic,[1] albumin was present in a high percentage of cases—on the second day of disease 100 per cent. Casts and renal epithelium undergoing granular degeneration were present in 50 per cent. on the third to fifth day. Granular casts and renal cells were the commonest. Hyaline casts were frequently present, and in some of the more severe cases epithelial and even blood casts were found.

On the whole, the kidney changes were greater in the present outbreak (see Table IV. and Graph); the Esbach

TABLE IV.—*Percentage of Cases of "Influenza" with Albumin and Casts in the Urine.*

Graph showing percentage of cases of "influenza" with albumin (continuous line) and casts (dotted line) in the urine on successive days of the disease.

reading on the third to fourth day was often 2 to 3 parts per 1000. These higher readings were seen for the most part only in cases showing definite chest signs. Moreover, the albumin continued to be present over a longer period, in some instances not clearing away until the twenty-first day of disease. In many cases the albumin gradually diminished in amount from the second day of disease, disappearing on the seventh, eighth, and ninth days, only to return when the patient was given an increase in diet or allowed out of bed.

In those cases confined to bed for a fortnight a slight "dietetic" rise was apparent about the ninth day; this soon disappeared, reappearing quickly when the patient was allowed up on the fourteenth day. Certainly the amount was small, but its significance is obvious in that we have seen patients return to duty only to relapse, with distinct albuminuria and œdema of the eyelids. This point we wish to emphasise on account of men who have mild attacks of influenza and are discharged from hospital at the end of a week or so. They return to duty, often up the line, where they run the risk of developing nephritis. Several such cases have come to our notice. It is of the utmost importance that all influenza cases should be free from exposure to the elements and hard work for at least three weeks after the acute symptoms subside, otherwise in the long run the health and efficiency of the fighting forces is diminished.

THE LEUCOCYTE COUNT.

Daily total and differential leucocyte counts were done on 12 cases over a period varying from 5 to 21 days. Individual counts were made on 20 cases. The daily counts were always taken at the same hour of day (all were collected between 10 and 11.30 A.M.), with the same instruments, and by the same observer in each case. The total white counts were mounted three times and the leucocytes on the 256 squares of a Thoma-Zeiss hæmocytometer slide counted with each mounting. This routine eliminated as far as possible errors of technique.

A critical survey of the results obtained show three distinct types of leucocytic curves in the present "influenza" epidemic, viz.:—(1) Influenza uncomplicated; (2) pneumonic form of "influenza"; (3) lethargic form of "influenza."

1. *The influenza type* is depicted in Charts 1 and 1A.

The salient features are a total leucocyte count a little below normal in the early days of the disease, and a leucocytosis of moderate degree (10,000 to 15,000 per c.mm.) sets in from the fifth to seventh day, this being most marked when the patient gets out of bed and goes about (20,000 per c.mm.). The absolute number of lymphocytes and neutrophil polymorphs (neutrophils) are slightly below the normal on the first two days of the illness; they soon recover their normal proportions, the lymphocytes recovering first. There is from now, as long as the fever lasts, a slight relative and absolute lymphocytosis, followed by a neutrophilia when convalescence sets in. The eosinophils and basophils are much decreased or absent during the pyrexia, but soon reappear when the fever subsides. (Table V.)

2. *The pneumonic type* shows a striking contrast to the above.

Distinct leucocytosis is present from the onset, and the total white count never falls below normal, unless death occurs, when either a leucocytosis or leucopenia may supervene. The leucocytosis varies from 15,000 to 30,000 per c.mm. (See Chart 2 and Table VI.) Often the highest counts are found after the temperature has fallen to and remained normal. This leucocytosis gradually lessens during convalescence unless complications arise.

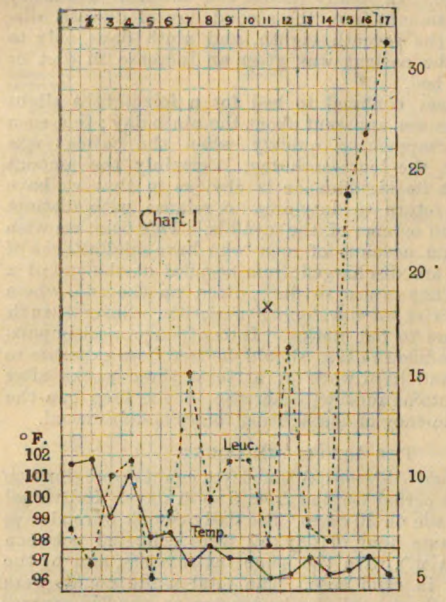
There is a relative and absolute increase in the neutrophils in the first few days of the fever, followed the next few days by a fall to normal of the number of neutrophils per c.mm., while the lymphocytes are subnormal. After the fifth day relative and absolute neutrophilia again becomes marked, and although the total number of lymphocytes increases it only reaches the normal line. Eosinophils and basophils disappear during the fever and reappear when the temperature returns to normal. If complications ensue the eosinophils disappear again. (Table VI.)

3. *The lethargic form* is quite distinct from either type 1 or 2. An absolute decrease in leucocytes (2000 to 3000 per c.mm.) is present from the first. This leucopenia lasts 7 to 12 days, at times remaining at a more or less constant level, at others slowly rising until convalescence sets in. The onset of convalescence is marked by a distinct increase in the total number of white blood corpuscles (10,000 to 15,000 per c.mm.) (Chart 3.) In those cases where death takes place the leucopenia becomes more and more pronounced as the end draws near. (Chart 4.)

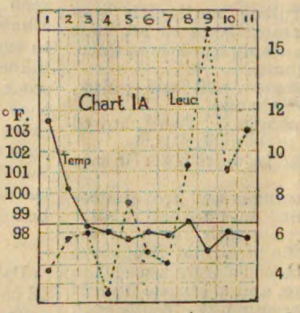
All the normal varieties of white corpuscles show an absolute decrease in their numbers during this leucopenia. The neutrophils, eosinophils, and basophils are most affected, the lymphocytes less so. With convalescence relative and absolute neutrophilia gradually establishes itself. (Table VII.)

EXPLANATION OF CHARTS.

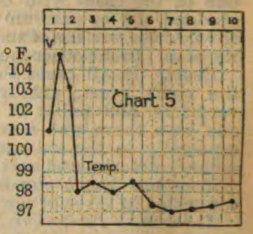
In all the charts the continuous line gives the temperature (key on left-hand margin); the interrupted line the leucocyte count in thousands per c.mm. (key on right-hand margin). The numbers at the head of the chart refer to the day of disease.



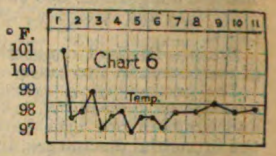
Leucocyte Count, Type I. Note the relatively low count during the febrile period, followed on the seventh day and onwards by a distinct leucocytosis. At × the patient was up for the first time.



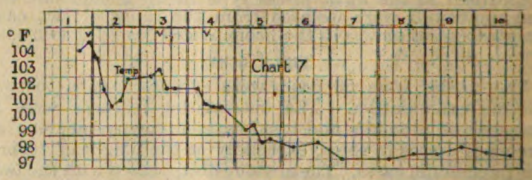
Note the leucopenia during febrile period, followed by a leucocytosis on the eighth day. This case was from the July epidemic.



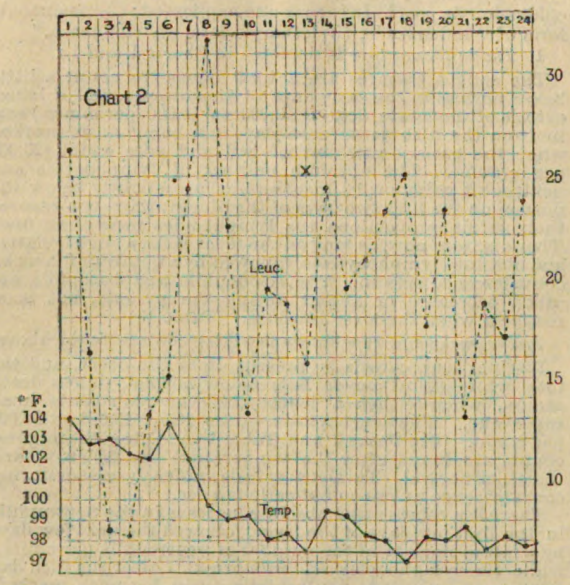
At V 0·5 c.cm. of prophylactic vaccine was given. Note the high initial temperature and the rapid return to normal.



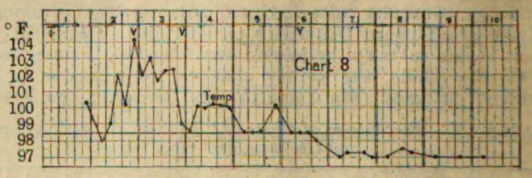
This case received 0·5 c.cm. of the prophylactic vaccine five days previous to the onset of influenza. Note the short course.



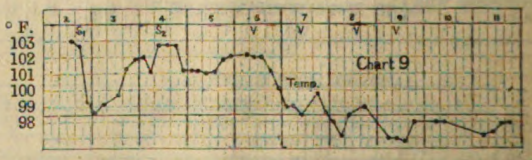
This case was admitted with definite pulmonary symptoms. Vaccine treatment (V, V, V, dose 1 c.cm.); short course; uninterrupted recovery.



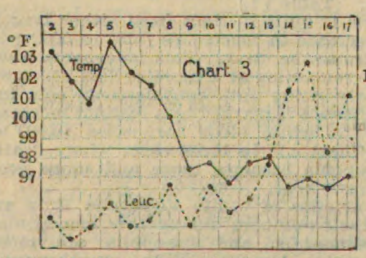
Leucocyte Count, Type II. Note the distinct leucocytosis throughout. At × onset of empyema.



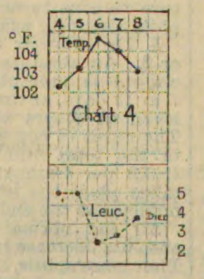
At V, the second day of disease, when the temperature reached 104·2° F., the first inoculation of 1 c.cm. curative vaccine was given. The dose was repeated on the third and sixth days. General improvement set in after vaccine treatment was started.



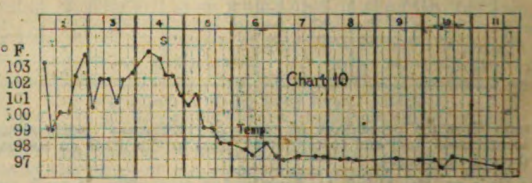
At S_1 20 c.cm. of antistreptococcal serum were given subcutaneously; at S_2 another 10 c.cm. Note the fall in temperature after the serum injections. At V, V, V, V daily inoculations of curative influenza vaccine were given to hasten resolution.



Leucocyte Count, Type III. Recovery. Note the leucopenia lasting 13 days, followed by a slight leucocytosis.



Leucocyte Count, Type III. Continued leucopenia up to the time of death.



At S, the fourth day of disease, 20 c.cm. of antistreptococcal serum were given subcutaneously.

Charts 9 and 10 may be compared with Chart 11, shown on the opposite page. This chart illustrates the failure of serum given after the fifth day.

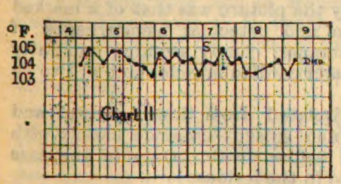
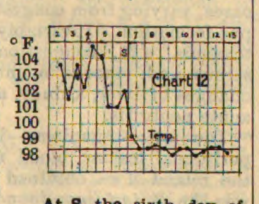
What the exact significance of these different leucocyte curves is it is difficult to say. The variation may be due to differences in the infecting agents, or the defensive and recuperative powers of the individual. Bacillary infections are frequently associated with a leucopenia, micrococcal infections with leucocytosis. We are inclined to the view that one organism—perhaps *B. influenzæ*—is responsible for Type 1, and when the infection is coccal there is either a good reaction on the part of the body causing a leucocytosis to develop, or the defensive powers are low and a leucopenia results. Generally speaking, a leucocytosis is a good sign, a persistent leucopenia is serious. In the latter case it is advised that a dose of mixed influenza vaccine (curative) be given to try to produce a leucocytic reaction. Serum is of no avail, for with it we have found a leucopenia.[4]

One other point worthy of mention is the disappearance of the eosinophils, not only when there is actual fever, but also with approaching fever or sepsis with low fever. Their return is of good omen. We have repeatedly noticed them disappear with the febrile stage of pneumonia, reappearing as defervescence takes place. In cases where an empyema supervened the eosinophils were absent from the peripheral blood prior to the condition being diagnosed clinically. (Table VI.)



At S 30 c.cm. of antistreptococcal serum were given subcutaneously. The dotted lines indicate where the temperature was reduced by sponging.



At S, the sixth day of disease, an inoculation with 18 c.cm. of anti-streptococcal serum was given. Note the fall of temperature to normal on the seventh day.

VACCINE TREATMENT.

The vaccine prepared by us was made from micro-organisms isolated from severe cases in the present epidemic. Most of the streptococci and pneumococci were obtained from post-mortem examinations. The vaccine was used (1) as a prophylactic and (2) as a curative. It consisted of the following micro-organisms:—

Streptococcus (a mixture of short and long chain streptococci from six severe cases) ... ... } 50 millions each per c.cm.
Pneumococcus (a mixture of pneumococci from six cases) ... ... }
Micrococcus catarrhalis (a mixture from two cases) ...
Bacillus influenzæ (a mixture from two cases) ... ... } 20 millions each per c.cm.
Meningococcus (a mixture from two cases) ... ... }

First dose = ½ c.cm. Second dose = 1 c.cm. (seven to ten days later). The curative dose was made up a tenth of this strength, and given daily in some cases, in others every second day.

Since the preparation and use of this vaccine we note that the conference held at the War Office on Oct. 14th,

1918,[5] recommended that the vaccine for influenza should consist only of *B. influenzæ*, pneumococcus, and streptococcus. We still continue to incorporate the *Micrococcus catarrhalis* on account of its common occurrence (72 per cent. in this epidemic); its frequency and advisability as an ingredient of an influenza vaccine has been commented on by others.[6] On account of the cases of cerebro-spinal meningitis accompanying influenza, the meningococcus was added to the vaccine. The present disease apparently varies according to the number and virulence of one or more of these organisms, and so the "blunderbuss" method of treatment is forced upon us.

Prophylactic Vaccine.

This has been administered to several hundred people, the local and general reaction being slight, passing off completely in 24 hours, although some cases complained of local tenderness for 48 to 72 hours, but on inspection the cause was usually found to be injury to some small vein at the time of inoculation. There is little or no fever. A few cases have complained of some depression after the second inoculation. All the persons inoculated have continued their daily duties without experiencing any inconvenience.

We confine our attention in this report to the inoculated and uninoculated cases in one institution.

The total number of persons in the institution was 305. Of these, 156 were inoculated and 149 uninoculated.

The case-incidence of the inoculated was 8 in 156 (i.e., 5 per cent.); amongst the uninoculated 18 in 149 (i.e., 12 per cent.).

All the inoculated persons who developed influenza had only mild attacks. Four of the eight attacked had slight fever and malaise at the time of inoculation and definite fever (102° to 104·8°) within 24 hours. This febrile period terminated in 48 hours, in contra-distinction to the seven-day course of the uninoculated. (See Chart 5.) The associated albuminuria disappeared within five days, convalescence being well established by the end of a week.

The protective influence of the vaccine is even more striking if the incubation period is taken as 40 hours.[7] The above four cases should then not be counted, thus reducing the disease incidence amongst the inoculated to 2·5 per cent. Of the remaining cases two developed the disease five days after the first inoculation, the other two four days after receiving a second injection. In each of these four cases the fever was slight (100°–101·5° F.), the temperature returned to, and remained, normal after 24 hours. (Chart 6.) There were no pulmonary symptoms in any of the inoculated cases.

The 18 uninoculated cases who fell victims to the disease had typical attacks with a five to seven day course in the milder, and a more prolonged one in the complicated cases. Pulmonary involvement was distinct in seven of the cases.

It is not claimed that the above vaccine is an absolute preventive, but we certainly think it will abolish or considerably modify the toxic type of the disease. The argument that vaccine treatment during the epidemic renders people more susceptible to infection carries little weight when the short and comparatively mild course of the disease in the inoculated is considered.

Curative Vaccine.

The dosage used by us in all cases was 1 c.cm. containing:

Streptococcus	5 millions.	Meningococcus ...	2 millions.
Pneumococcus	5 ,,	*B. influenzæ*	2 ,,
M. catarrhalis	5 ,,		

The first injection was given as soon after admission as possible, and repeated daily until the temperature fell to normal.

The vaccine was used alone in cases giving a temperature of 103·5° F. or under; for cases with higher temperatures 20 c.cm. of polyvalent antistreptococcus serum was given subcutaneously, thereafter 10 c.cm. being administered daily for three or four days. At times vaccine treatment was combined with the serum. (See Charts 7 and 8.)

In no instance had the vaccine any ill-effect, but, on the contrary, several cases cleared up rapidly, the fever passing off in three or four days, at times sooner, even when the initial temperature was high and the patient obviously ill. Furthermore, the albuminuria and renal casts disappeared more rapidly in the cases treated with vaccine than in those treated with drugs only.

In a few cases of the pulmonary type, when there was no sign of abatement of the disease on the seventh day, 1 c.cm. of the vaccine was injected daily, the result being a fall of the temperature by lysis. This, of course, may have been a coincidence, but in two cases aspirin and various other drugs failed to affect the fever, whereas the temperature gradually fell about 24 hours after the vaccine treatment started.

Personally, we are convinced that the vaccine does no harm, but frequently promotes a quick recovery. Such vaccines should be administered as early in the disease as possible. The short acute course of two cases inoculated the first day of the disease with a full prophylactic dose suggests that all cases seen early may have their course cut short by a large dose of the vaccine before toxæmia has time to set in.

SERUM-THERAPY.

Briefly, cases treated early in the disease have a far greater chance of recovery than those treated late, as a glance at Table IX. shows. All the cases were severe. Of those injected with serum before the sixth day all recovered—i.e., six out of six; while of those injected after that day—six all told—four died (i.e., 66 per cent.).

TABLE IX.—*Day of Disease of First Serum Injection.*

Case.	Day.	Result.	Case.	Day.	Result.	Case	Day.	Result.
22	2	Recovery.	48	5	Recovery.	26	8	Died.
19	4	,,	16	5	,,	34	10	Recovery.
38	4	,,	2	7	,,	5	10	Died.
33	5	,,	27	7	Died.	21	13	,,

In Chart 9 the effect of the administration of serum early in the disease is well shown. This patient had definite pulmonary signs, but from the third day there was a distinct general improvement in the case; recovery from the seventh day was uninterrupted. Curative vaccine was given daily on the sixth to ninth day inclusive. Chart 10 shows the effect of the serum given on the fourth day of the disease. These charts should be compared with No. 11, illustrating the failure of serum given after the fifth day.

It is apparently necessary to emphasise the importance of not laying too much stress on vaccine or serum treatment delayed until the sixth or seventh day of disease, as we have seen much credit given to most forms of treatment solely from the results as depicted in Chart 12. In such cases the sudden fall in the temperature and general improvement of the patient is most likely due to the natural termination of the pneumonia on those days.

These observations on antistreptococcus serum apply solely to that prepared by Messrs. Burroughs, Wellcome, and Co.

SUMMARY.

1. The results of blood cultures show that there is septicæmia in some of the cases. Most of these have a fatal issue. The figures at our disposal are insufficient to make any definite statement as to whether this septicæmia is present early in the disease or only as a late symptom. That it is a late symptom is borne out by the fact that streptococci were isolated from the heart's blood after death in cases where the blood-culture result was negative early in the disease.

2. The causal micro-organism of the septicæmia is not the same in all cases.

3. The examination of sputa and posterior nasal swabs shows a *mixed* and fairly constant flora. Such organisms as streptococcus, pneumococcus, *Micrococcus catarrhalis*, and *B. influenzæ* are present in a high percentage of cases; in all instances over 66 per cent., except in that of *B. influenzæ* (46 per cent.).

4. The predominating organism varies, being: *Micrococcus catarrhalis* in 34 per cent., streptococcus in 30 per cent., pneumococcus in 26 per cent., *Staphylococcus aureus* in 8 per cent., and *B. influenzæ* in 2 per cent. of the cases. It should be noted that in only one of this series of cases was Pfeiffer's bacillus found to be the predominating organism.

5. Post-mortem examinations show lung lesions in all cases, varying from congestion and œdema to pneumonia and pus formation. Invariably the picture was that of a marked toxæmia, e.g., congestion and petechial hæmorrhages of serous and mucous membranes, cloudy swelling and fatty changes of liver, kidney, and cardiac muscle, and in two an acute nephritis.

The micro-organisms—isolated from lung, pleural and peritoneal lesions, blood and spleen—coincide closely with the mixed flora obtained before death. Only in one case was the *B. influenzæ* found in the lesions.

6. Isolation of diplostreptococci from the heart's blood and spleen post mortem supports the view that a true septicæmia is present.

7. Albuminuria is a constant feature. Casts are present in 50 per cent. of the cases. That there is a definite

nephritis in some cases is clear from the appearance of epithelial and blood casts, and fully substantiated by the post-mortem findings.

8. There is sufficient evidence in all cases that the renal condition warrants especial care during convalescence.

9. The daily leucocyte counts show that all cases do not conform to one type. Broadly speaking, a leucopenia, if continued, is of bad, a leucocytosis of good, prognostic import. A marked leucocytosis after the eighth or ninth day, especially if the eosinophils are much decreased or absent, strongly suggests complications. Incomplete recoveries and the oncoming of a relapse can often be diagnosed from the blood picture, even when the clinical signs are slight or absent.

10. Prophylactic vaccination on two, preferably on three, occasions with a weekly interval between each inoculation is without risk, increases the immunity of the individual, and prevents the onset of pulmonary complications. Should the inoculated develop influenza the course of the disease is invariably mild.

11. As regards treatment, we recommend that: (1) In very early cases a full dose of prophylactic vaccine should be administered. No further doses to be given at least for several days. (2) Cases seen on the first day, or later, provided the temperature is not above 104° F. or the patient markedly toxic, should be given 1 c.cm. of the curative vaccine daily until temperature falls to normal, unless symptoms become worse. (3) Those cases which show high pyrexia or toxic condition from the start should be treated with polyvalent antistreptococcus serum, 20 c.cm. should be administered subcutaneously *as soon as possible*, and followed by daily injections of 10 c.cm. for three or four days. With this treatment calcium lactate, gr. 5, should be given daily for 7 to 10 days to ward off serum sickness. Vaccine may be combined with this if required.

There is no reason why other forms of treatment should not be combined with the above.

CONCLUSIONS.

The variety of clinical types, as depicted by symptoms and leucocyte counts, the mixed bacterial flora obtained from blood cultures, sputa, throat swabs, and at post-mortem examinations, render it quite impossible to assign any one specific virus as the causal organism. The bacillus of Pfeiffer was found in 46 per cent. of the cases, and only as the predominating organism in one case out of 50. It may possibly be the primary agent, and the other micro-organisms found secondary, but we see no reason why this should be the case when such micro-organisms as the streptococcus and pneumococcus are far more frequently found in the pathological lesions in this disease.

Although there is the remote possibility of there being an underlying ultra-microscopic agent at work in lighting up the epidemic, one cannot conceive a *single* activating agent in a disease attacking its victims in such diverse ways.[8]

In our opinion the presence of a more or less constant group of micro-organisms renders each individual the potential possessor of the specific symptoms caused by each virus. This will depend on various factors, such as the number and virulence of the micro-organisms, the resistance of the patients, and intercurrent diseases.

From the foregoing results we are forced to conclude that the malady we have been studying is not a simple but a "compound" disease.

We are greatly indebted to Lieutenant-Colonel T. S. Allan, R.A.M.C. (T.), O.C., Military Hospital, Hampstead, and Lieutenant-Colonel F. F. Muecke, R.A.F. (M.S.), O.C., R.A.F. Central Hospital, Hampstead, for permission to carry out this work, and to Major W Byam, R.A.M.C., and Surgeon-Lieutenant O. H. Gotch, R.N., and other medical officers concerned for access to their cases. Special thanks are due to Miss Samuel, B.Sc., for her loyal assistance throughout.

SOME OBSERVATIONS ON THE MORE SEVERE CASES OF INFLUENZA OCCURRING DURING THE PRESENT EPIDEMIC.

BY SIR THOMAS HORDER, M.D. LOND.,
ASSISTANT PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL, ETC.

IT is as yet too early to write a full and adequate account of the prevailing epidemic of influenza. Some time must still elapse before the clinical and pathological experience of different observers can be collated, and before the statistical results of those who have been in charge of large numbers of cases under Service conditions can be properly interpreted. But it may be well even at this stage to put on record certain observations of a general sort, with such reflections concerning them as may lead to critical analysis by others of their own experience. These observations being more or less disjointed, they are set out under certain convenient headings.

I.—*The Pyrexia.*

The temperature rises abruptly with the invasion symptoms, which are not nearly so painful in many cases as they were wont to be in former recent epidemics, and reaches 103–4–5°. In the majority of cases it remits or intermits. It also usually "responds" at the early stage to various antipyretic drugs, falling with a sweat, and rising again. If no such response occurs, assuming an adequate dose has been given, this is a bad sign; the case is likely to prove one of the more serious sort. *With this experience it is unwise to repeat the drug.* If the initial temperature rises to a high level and continues there without remission the case will probably be one of the intensely toxic kind; it may even fulminate and prove rapidly fatal. If it be a case of the lesser degree of these two conditions, the condition may in three to six days become hyperpyrexial, with dusky facies, delirium or stupor, tremor, dry tongue, shallow respirations, and a deceptively low pulse-rate in proportion to the high temperature, which may reach 106° or higher. If neither of these two very serious conditions ensues the temperature continues to remit or intermit until about the fourth to fifth day, when it may suddenly rise to a higher level and remain there, indicating some acute pulmonary event, which in the majority of instances turns out to be pneumonia. In this case the subsequent course of the pyrexia depends upon the developments in the lung (*vide* § II.). If the pulmonary event is a broncho-pneumonia, or a purulent bronchitis, or a pleurisy, the higher level of the pyrexia remains but the temperature intermits. Should no pulmonary event supervene other than the congestion common to nearly all severe cases, the temperature usually begins to fall about the fifth or sixth day, and reaches normal, by a process of lysis, about the tenth to twelfth day. In a few cases a crisis is observed, and in rather more a pseudo-crisis, followed by a recrudescence, and this recrudescence is very prone to be accompanied by an acute pulmonary complication. The pyrexia sometimes terminates rapidly with the expectoration of a large amount of bloody sputa (*vide* § III.), as if a pneumonic process "aborts." Once it is down the temperature may remain subnormal for a few days and gradually return to normal. True relapses are uncommon in the absence of gross mismanagement. A few cases show a quotidian intermitting temperature (to 99 5–101°) for several days, it may be for two or three weeks, after the main fall in the pyrexia, and the rise is sometimes in the morning and not in the evening.

The question of the existence of *apyrexial cases* of influenza is, I think, to be answered in the affirmative. Though it is scarcely possible to make a diagnosis in the absence of a raised temperature, I have met with instances of relatively severe prostration associated with pulmonary catarrh, lack of heart tone, and sweats without fever that were probably due to influenza. They have generally, but not always, been in persons over 60 years of age. In this connexion it is well to remember that typhoid fever may be apyrexial in elderly patients. There is an obvious practical point as regards treatment underlying this consideration.

II.—*The Respiratory System.*

The respiratory system is affected in a large number of ways. But it is perhaps worthy of note that the "catarrhal"

element, in so far as the mucosa of the upper air passages is concerned, seems much less in evidence during this epidemic than during former ones. Not only is this so in the course of the disease, it is seen also in the relative infrequency of catarrhal sequelæ. But certain considerations warn us not to take this fact to mean that we are not dealing with the same virus as was responsible for the epidemics of influenza in which catarrhal manifestations were very prominent: (1) The bronchiolitis which is so common a feature in many of the severe cases is essentially a catarrhal process; (2) the so-called "simple febrile" type of influenza occurring in other epidemics was a catarrhal; (3) different epidemics of well-known diseases (e.g., scarlet fever) are prone to exhibit different features, though probably due to the same virus.

The respiratory manifestations extend from laryngitis and tracheitis through bronchitis to lobular and lobar pneumonia and pleurisy, both "dry" and with serous or purulent effusion. But the characteristic feature, and one which is rarely absent in any severe case, is a condition of capillary bronchitis with intense pulmonary congestion. It may be unilateral or bilateral, is more often basal than apical, but is not seldom universal. The physical signs are copious fine râle (crepitation), with impaired vesicular sound, and, less often, impaired percussion tone. The degree and the extent of this lesion vary from day to day. It is undoubtedly the chief cause of the cyanosis which is so common a feature; it contributes the bloody sputa which are not seldom seen and it embarrasses the heart and, indirectly, the central nervous system. It may be termed the essential lesion of the disease. *Even when consolidation of the lung is present, this is quite often an incident by comparison, and if the patient dies he dies with the consolidation rather than of it.* When asked "if the patient has pneumonia" we try to give some comfort by replying that he has not got it yet, when the correct answer would be that he has the first stage of pneumonia already. Whether the patient dies or lives depends upon the extent of this pulmonary congestion, together with the intensity of the toxic process in relation to the central nervous system. It is extremely difficult to form an estimate of how many cases of the severer sort, with this pulmonary engorgement, develop areas of consolidation, because routine examination of the back is impossible, and, indeed, is inadvisable. But the proportion is probably larger than is usually thought.

It is interesting to note that a "sthenic" pneumococcal lobar pneumonia may be, as it were, an intercurrent event, leading to its own signs and temperature curve, and, after resolution, leaving the patient in much the same condition as it found him, save for the further weakness left by the superadded disease. Post-mortem observations show how varied is the flora associated with the incomplete pneumonic areas in fatal cases—pneumococci are present, as would be expected, but streptococci, *S. aureus*, and Pfeiffer's bacillus are found in varying degrees, and not infrequently in much larger numbers than the pneumococci. One sign of the incomplete nature of the process of hepatisation in many cases is the relative infrequency of pleuritic rub over the consolidated area as compared with ordinary cases of pneumonia. The duration of the pneumonic patch is very variable. It may endure for a day only, resolving rapidly with crisis, or it may persist after the pyrexia has gradually ceased (*vide* § IV.). *In the main its existence depends upon the state of the patient's general condition; it clears slowly as this mends, or it spreads rapidly as this lapses.* Cases of true broncho-pneumonia do not seem very common—the name is sometimes given in error to pneumonia of the lobar type when the patches are small and bilateral—apart from infants and little children. Nor is pleurisy common apart from pneumonia. The apparent relative increase of streptococcal, as against pneumococcal, empyemata during recent months may be accounted for by the cases being secondary to influenza with pleurisy.

III.—*The Sputa.*

The sputa vary considerably. They may be absent throughout the whole course, even of very severe cases, including some in which there is intense and widespread pulmonary congestion. When present they include the tenacious mucus of acute tracheitis and bronchial catarrh, the muco-pus and pus of purulent bronchitis, and the rusty sputa of lobar pneumonia. About these sorts of sputa there is nothing characteristic of the disease. Two other kinds occur, however, with some frequency, and both of them are very typical of severe influenza. 1. Bright pink frothy mucus, produced without difficulty and sometimes in large amount, it may be as much as a pint or more in 24 hours. The fresh rose-red colour of this expectoration is very striking, and suggests strongly that it results from acute inflammatory œdema of the lung, which indeed it does, as proved by post-mortem evidence. At times this material is expelled involuntarily during cough and some of it may spurt from the nostrils. 2. Tenacious mucus, less viscid than in lobar pneumonia, of greater amount, and differing also in colour, which may be of several hues—red, brown, saffron, and various tints of green, all of these being present at the same time. Seen in a white earthenware vessel, this type of sputa is very striking and is highly diagnostic. Dr. Hurtley, to whom I gave a specimen of these green sputa, tells me that the chief band present in the spectrum was that of hæmatoporphyrin. Both of these sorts of sputa may occur in the same case and in the order as regards time that they are here described.

IV.—*The Post-febrile Period.*

In a large number of the severe cases, and in not a few of the mild ones, a state of exhaustion quite disproportionate to the duration of the illness follows the pyrexial period. Careful examination often reveals no incriminating feature in any organ. The degree of prostration may be profound, and may be much more trying both to patient and doctor than was the disease itself. Profuse night sweats are common. Various other immediate sequelæ are to be noted.

1. *The nervous system.* The "higher centres" suffer chiefly; marked depression is common, emotional instability is often seen, and suicide is by no means rare. In a few cases a condition of amnesia which was present during the febrile stage persists for some days, then clears away. Neurasthenic states and insomnia which were present before the illness tend to be accentuated, or, if they were yielding to time and treatment when the disease appeared, they are prone afterwards to give further trouble.

2. *The heart.* In most of the instances in which the heart is left in an unsatisfactory state—and they are very many—there is no systematised defect that can be discovered on examination at the bedside. Despite the objection of some cardiologists to the use of the term in this connexion, we can but call many of these hearts "weak." It is reasonable to postulate a state of fatigue, whether of nerve or muscle or both, though no doubt a condition of toxic myocarditis also occurs. But as the symptoms pass off in many of the cases after a few days of continued recumbency, it is not likely that this last-named condition is present in many of the patients who exhibit cardiac inadequacy. Bradycardia of simple type is common, the pulse dropping to 50, 40, and even to 30. This state of things can be shown not to be a dissociated effect—i.e., not a state of heart-block. "Heart attacks," chiefly of the type termed "cardiac asthma," are not uncommon; *the appearance of one of these attacks may be the first sign to an unsuspecting patient or to her friends that all is not well.* These attacks, though very alarming, are rarely fatal. They are seen more often in women than in men. The cardiac element in the attack may be associated with, or may be overwhelmed by, obvious neurosis; the dissociation of the two elements is sometimes exceedingly difficult and the prognosis is correspondingly obscure. Of the ultimate effect of the present severe forms of influenza upon the nerves and upon the hearts of the patients we cannot yet speak.

3. *The pulmonary system* sometimes shows sequelæ during the post-febrile period. The most common condition is the persistence of an area of chronic congestion at one base, with or without a suspicion of pleural involvement. This "soppy" base may be present for weeks, or even for months. (? Whether some of the cases in which this condition is known to have persisted for years are not originally influenzal in origin.) Pneumonic patches may be found during this period. They are of two kinds: (*a*) areas of unresolved pneumonia, and (*b*) what may not inappropriately be termed "residual consolidation"—patches of pneumonia that appear with, or just after, the fall of temperature. These areas usually clear quietly and slowly, their duration depending chiefly upon the progress made by the patient in tone and strength: the more rapid the general improvement the quicker does resolution take place. Pleural effusion may be discovered during the afebrile stage and may call for aspiration. The fluid is serous, is either sterile or contains scanty streptococci, and the occurrence of the effusion by no

means indicates that the patient is tuberculous. No doubt the discovery of some of these pulmonary lesions during the post-febrile stage is due to lack of adequate examination during the more acute period of the disease, but this is certainly not the explanation in all cases.

V.—*Diagnosis.*

Experience of the present epidemic throws light upon the nature of many obscure cases which occurred during the past summer. It is now obvious that these were sporadic cases of the now prevalent disease. As in some other epidemic and endemic diseases it is common to see the main wave of incidence preceded by small ripples, so in influenza. (Cf. cerebro-spinal fever.) This fact leads to the appearance of individual cases, often quite severe, the nature of which, in the absence of bacteriological or other criteria of an absolute kind, remains obscure until a flood of cases of a similar sort establishes the diagnosis.

Early in July two boys and their mother were admitted (from the same house) to St. Bartholomew's Hospital. The mother's illness took the form of a moderate pyrexia with diarrhœa. Both boys were gravely ill, with high continued fever, relatively low pulse-rate, marked cerebral irritation—in one there was definite "meningism" leading to lumbar puncture with a view to exclude cerebro-spinal fever—dry tongue, and constipation. A leucopenia was present in both cases. There was widespread pulmonary congestion, but no signs of pneumonia. There were no spots, the spleen was not palpable, blood cultures were negative, and no agglutination was obtained against *B. typhosus* and *B. paratyphosus*. All three cases recovered. In face of these data no diagnosis could be, nor was, made. How simple the diagnosis would be to-day!

I can think of no less than six cases of severe illness, seen during the summer, with high temperature, marked nerve prostration, leucopenia, and negative blood culture, in all of which the diagnosis of typhoid or para-typhoid would have been made but for the absence of agglutination. In four of them the degree of pulmonary congestion was not more than is frequently seen in typhoid fever, although in the other two cases it certainly was. But *the likeness of severe influenza to typhoid fever* may be closer than this. In August I was asked to see a young doctor on the tenth day of his illness because he was passing a large quantity of blood by the bowel, following upon a dose of calomel. The onset of the disease had been sudden, with a rigor. When I saw him he was running a persistently high temperature (104–5°), his pulse-rate was not above 90, he was tremulous, delirious, had sordes on lips, his face was dusky, and his abdomen was distended. He had no typhoid spots and his spleen was not palpable. There was congestion of the base of the right lung, but not to a marked degree. He continued to pass blood freely for 48 hours. A blood culture was negative, as also were agglutination tests. He developed an incomplete pneumonia and died on the seventeenth day of his disease. I have recently seen a similar case in which the enterorrhagia followed the use of an enema.

By no means all the pneumonia now prevalent is influenzal. There are a goodly number of cases of uncomplicated pneumonia of pneumococcal origin, both the lobar type in adults and the lobular type in children, and the prognosis in most of them is, as usual, not unfavourable. This should be remembered in view of the present very natural popular dread of a dire result whenever pneumonia is diagnosed. Careful analysis of the mode of onset of the pulmonary event, the clinical features of the case, and, when possible, bacteriological results will usually lead to a correct differential diagnosis.

Poliomyelitis is evidently rife at the present time, contrary to the usual seasonal incidence of the disease. The early symptoms may easily be mistaken for influenza when the latter disease is so ubiquitous. I have recently met with a small outbreak of poliomyelitis in a boy's school, in which 150 boys out of 200 were affected by influenza. Six boys fell victims to the virus, all of them 15–16 years old and five out of the six were in the same house. In two of the cases it is certain that the influenza preceded the poliomyelitis by a definite, though short, interval; in one it is probable that the reverse order of infection was observed; in the remaining three cases both infections would seem to have occurred simultaneously. It is not at all unlikely that some of the cases of "neuritis" following influenza, in children and in young adults, are really cases of this disease. The importance of diagnosing the condition as early as possible is obvious.

VI.—*Prognosis.*

Despite the protean nature of the disease and the many grades of severity that the clinical picture may assume, prognosis is not found to be so difficult as is often supposed. The real crux in the early stages of the disease is the question, Which cases are going to be severe and which are going to be mild? The degree of suddenness, or rather the degree of initial intensity, of the onset, does not decide, nor the height of the pyrexia during the first 48 hours, nor the amount of the patient's discomfort. *If the patient comes under treatment late this fact is of bad omen;* nearly always the case is severe, very frequently it is fatal. 1. Fulminating cases are, of course, rapidly fatal; there is never any doubt as to their issue. 2. Next to the fulminating cases the outlook is worst in those patients who sink progressively into a state in which there are cyanosis, delirium or stupor, diminishing cough, high continued fever, and physical signs of extensive pulmonary congestion. *If this condition is reached rapidly, such as any time before the sixth day, the case is usually fatal.* 3. Of less gravity, but still with a very serious outlook, are the cases in which after four or five days of moderately severe illness the temperature rises suddenly to a higher level, continues there, and signs of patchy consolidation of lung appear. 4. Cases of purulent bronchitis, with patches of broncho-pneumonia, cause great anxiety, but usually give time for treatment; they are more hopeful. 5. If a "sthenic" lobar pneumonia supervenes upon a fairly mild attack the prognosis is still less serious, even though, as already mentioned in § II., no complete crisis is likely to occur. 6. In simple pleurisy the outlook is good, whether liquid effusion arrive or not. 7. Bronchial catarrh is the least unfavourable of all the pulmonary events, and rarely leads to a fatal issue unless it be in the elderly and in infants.

Speaking of other than pulmonary complications, the following points appear to be in the patient's favour: an age which is below 20 or above 40 years, irregularity of the pyrexia as contrasted with high continued fever, catarrh of the upper respiratory tract and air passages, coarse as contrasted with fine râle on auscultation of the chest, muco-purulent sputa rather than tenacious and bloody mucoid sputa, strict correspondence of the temperature curve with the pulse-rate, absence of cyanosis, and a moist skin. In addition to the bad points to be inferred *per contra* from this list, the following also tell against the patient's chances: delirium, stupor, insomnia, persistent vomiting, and repeated diarrhœa.

Postscript on Treatment.

Further experience in the treatment of the more severe class of case now occurring has but confirmed the views expressed in THE LANCET of Nov. 23rd as to the great value of aero- and hydro-therapeutic measures. A free current of air, both in the room by means of widely open windows and over the patient's body by means of a "cradle" and very little bed covering, frequent sponging, the fearless use of the cold pack when hyperpyrexia is present: these measures are of greater service in the intensely toxic cases with high fever than are febrifuge drugs, which usually fail of their object and depress a heart which is already hard put to it to maintain the struggle. *In these very bad cases sweating does not occur, and it is useless to attempt to get it.* In them heat is lost from the body by radiation, and to this process many blankets are a deterrent and not an assistance. If the skin is losing heat by way of sweating well and good, let it be encouraged by warm blankets, but there is here no cause for much anxiety. The anxious cases are those in which sweating does not occur (I am speaking of the earlier stages of the disease), and in them the removal of heat and the consequent adjustment of the body temperature should be provided for in the manner above indicated. It may seem a matter of supererogation to point out this distinction, and yet it is one which is not infrequently lost sight of in practice. I am still more convinced of the necessity of caution against overfeeding, both as regards the quantity and the character of the food. So-called specific drugs continue to be very disappointing. The creasote and iodide mixture that has been advocated does not seem to justify itself, either with pneumonia present or not; it not seldom causes vomiting, and thus introduces an additional difficulty in the case.

THE USE OF VACCINES IN ACUTE INFLUENZA

AND INFLUENZAL BRONCHO-PNEUMONIA.

BY W. H. WYNN, M.D., M.Sc., M.R.C.P. LOND.,

HONORARY PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM; LECTURER ON CLINICAL MEDICINE, BIRMINGHAM UNIVERSITY; CAPTAIN, R.A.M.C.(T.).

THE object of this paper is to call attention to the successful results obtained by the treatment of acute influenza and influenzal broncho-pneumonia with adequate doses of vaccine containing *B. influenzæ*, streptococci, and pneumococci.

Principles of Treatment.

The recommendations of the Conference held at the War Office on Oct. 14th, which have been adopted by the Army and Local Government Board, show a certain timidity in the use of vaccines for treatment.[1] Whilst recommending prophylactic inoculations with, what I consider to be, entirely inadequate doses, they state that vaccine is most likely to be of service in the treatment of subacute and chronic cases, and recommend a dose of 6 million *B. influenzæ*, 20 million pneumococci, and 8 million streptococci as an initial dose. As regards severe cases of secondary broncho-pneumonia they do not recommend vaccine, but if it be desired to treat such cases an initial dose of 1½ million *B. influenzæ*, 5 million pneumococci, and 2 million streptococci is suggested.

The treatment of influenzal broncho-pneumonia in no way differs from the treatment of acute pneumonia and broncho-pneumonia due to other causes. In a paper in which I recorded the results obtained by the early administration of vaccines in acute pneumonia[2] it was urged that the best results were obtained by injecting an adequate dose as early as possible. 100 million pneumococci were given as an adequate dose for an adult man. Since then acute pneumonia has been consistently treated, not only by myself, but by many practitioners all over the British Isles, according to the principles laid down with excellent results. Broncho-pneumonias of all kinds have been similarly treated.

Influenzal broncho-pneumonia during an epidemic period resembles acute lobar pneumonia in that a suitable stock vaccine can be kept ready for use, whereas with other broncho-pneumonias time is lost in discovering the nature of the infection and making the appropriate vaccine.

For the treatment of influenza and its secondary broncho-pneumonia Lord Fisher's advice is appropriate: "Strike early and strike hard." The first moment the patient is seen is the time to inject, and the dose should be sufficiently large to produce a satisfactory response within a few hours. Hesitation and delay are fatal. Every case should be regarded as a serious one. Many cases beginning mildly rapidly get out of hand if untreated and prove fatal. Action must be decisive—offensive, not merely defensive. Drifters must not be sent into action when battle cruisers are required.

My practice is to inject, and advise others to inject, every acute case seen in the early stages of the disease, unless the patient is obviously beyond help. At first I used 50 million pneumococci, 50 million streptococci, and 30 million influenza bacilli as an initial dose in an adult, gradually increasing to 100 million and 60 million respectively if further doses were required. Now I more often begin with a dose of 80 or 100 million of all three organisms, and find more decisive results in aborting the disease are obtained. In a certain group of cases *B. Friedländer* was found, and for these this organism was added to the vaccine. These therapeutic doses are larger than those recommended by the War Office Conference for prophylaxis, and very much larger than those suggested for the treatment of acute cases. The pneumococci used in the vaccine were obtained from recent cases in primary culture, the streptococci were also recent strains and, as far as possible, in primary cultures. The influenza bacilli were partly isolated by myself, partly obtained from Messrs. Parke Davis, and Co.

Record of Cases.

Some hundreds of patients have now been treated on these lines by myself and by practitioners associated with me. During the present rush of work complete statistics are not yet available. Of cases directly under my care there has only been one death among those inoculated within 48 hours of the onset. Several doctors have told me that they have had no deaths in inoculated cases. The few cases here briefly recorded with their charts are taken from a large number. They are in no way exceptional, and are given as showing what may be expected of vaccine treatment in various types of the acute disease.

A. *Acute Influenza, Uncomplicated.*

CASE 1.—A young woman aged 26. Injected about eight hours after onset with 50 million pneumococci and streptococci, 30 million influenza bacilli. Respirations 30, pulse 96. Pains severe, suffused eyes. Pharyngitis. No complications. Temperature reached normal nine hours after injection. During the second night it rose again to 99·4° and thereafter remained normal.

CASE 2.—A man aged 40. Onset severe and rapid with shivering, intense pains, slight vomiting, furred tongue, explosive cough. Pulse 108, respirations 30. Injected about three hours after onset with 100 million of each organism. Temperature reached normal 24 hours after injection. Labial herpes appeared on the third day. No further rise of temperature, but some cough for four days.

CASE 3.—A boy aged 8. He left home for school at 8 30 A.M. and arrived back three hours later scarcely able to stand, shivering, giddiness, severe headache, and nausea. Injected at 1.30 P.M. with 20 millions of each organism. Temperature was then 102·6°. Next morning temperature had fallen slightly, but rose later to 103·8°. On the morning of the third day a dose of 40 million of each organism was injected. This was followed by a fall in the temperature, which reached normal during the afternoon of the fourth day. Weak breath sounds and sticky crepitations were heard at bases of both lungs. This was one of the very few cases of simple influenza which required a second inoculation to cause a fall in temperature.

These three patients were injected within a few hours of the onset, but other charts could have been given showing a similar fall of temperature when the initial dose was given after two, three, or four days of sustained temperature.

I have seen no similar charts in uninoculated cases. Occasionally mild cases are seen with a pyrexia of 48 hours, but a duration of 4 to 6 days is more usual. Occasionally a fall by crisis is seen in untreated cases, but lysis is the rule. As crisis has almost invariably followed a single adequate dose of vaccine in my cases of simple influenza at whatever stage of the disease, it is difficult to resist the conclusion that they are related as effect and cause.

B. *Acute Influenzal Broncho-pneumonia.*

CASES 4, 5, 6, and 7 may be taken together. The patients were all young men. They were typical cases of the moderately severe type. There were dullness, weak breath sounds, and many crepitations at the bases of both lungs, with small areas of bronchial breathing, moderate cyanosis, respirations 28 to 32, pulse 100 to 120. Blood-stained, frothy sputum in Cases 4 and 5, frothy muco-purulent in the other two. Considerable distress in all four. Case 4 was injected about 24 hours after the onset with 70 million pneumococci and streptococci and 40 million influenza bacilli. The temperature after first rising slightly fell rapidly and reached normal 24 hours after the injection. No further injection was required. Case 5 was not injected until the third day; the disease was of a more severe type, and a dose of 100 million pneumococci and streptococci and 60 million influenza bacilli was given, followed by a fall of temperature to 100°, then after a rise to 102·2° it reached normal early on the fifth day. As the temperature did not quite settle a second injection was given on the sixth day. Case 6 received a dose of 80 million of each organism on the third day, and had a normal temperature early on the fifth day. Case 7 reached normal 24 hours after an injection of 100 million pneumococci and streptococci, 60 million influenza bacilli.

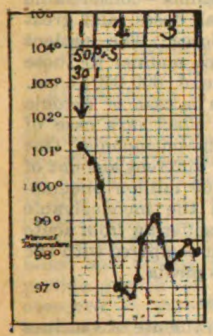
CASES 5, 6, 7, and 10 belong to a group of 17 patients from the same community admitted with influenza. Of these, 9 had broncho-pneumonia. Five not under my care were not inoculated and 4 died, the remaining 4 were inoculated and all survived. The cases, however, cannot be taken as strictly comparable, as three out of four of my cases gave rise to no special anxiety, although it is difficult to say what they might have become had the fever not been cut short.

C. *Very Severe Confluent Broncho-pneumonia.*

CASE 8.—A young woman aged 25. Symptoms began with great severity, extreme cyanosis, prostration, weak pulse, extensive signs throughout both lungs with large confluent patches at bases, sleeplessness, and delirium. Condition extremely critical for five days. Respirations reached 48, pulse 120. The first injection of 50 million pneumococci and streptococci and 30 million influenza bacilli caused a critical fall of temperature from 104° to 97°, a second dose on the fourth day was followed by a more gradual fall, after which the temperature remained normal. Two more injections were given later and were followed by general improvement. On the tenth day she had left femoral thrombosis.

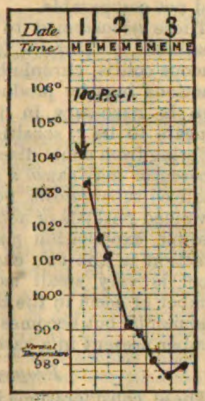
CASE 9.—A man aged 50. A case of the worst kind in a stout, flabby man with a bad alcoholic history. Enlarged liver, much albumin with casts and pus cells in urine. Very severe onset. Respirations 50 on first day. Pulse did not exceed 112, but was very feeble. At first much struggling and attempts to get out of bed, later muttering delirium and picking at bedclothes. Crepitations all over both lungs, large confluent patches involving the whole of both lower lobes, explosive exhausting cough with little sputum. Retention of urine. Much

1



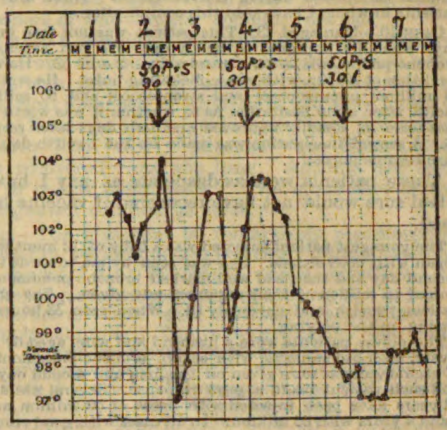
CASE 1.—Female, aged 26. Influenza, uncomplicated.

2



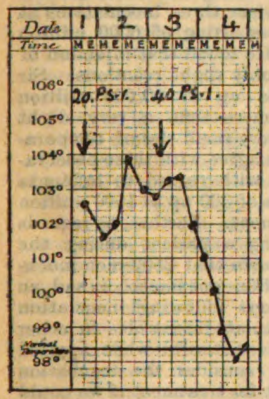
CASE 2.—Male, aged 40. Influenza, severe onset.

8



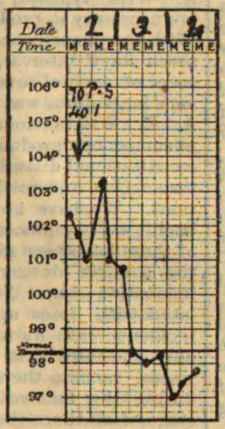
CASE 8.—Female, aged 26. Very severe confluent broncho-pneumonia.

3



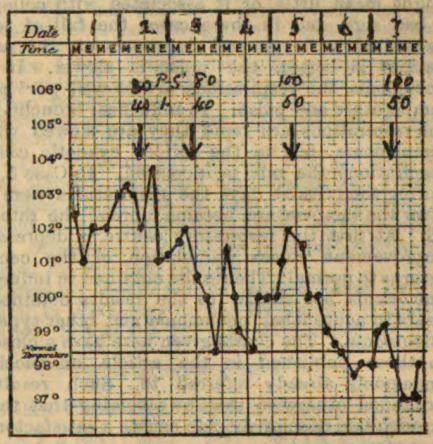
CASE 3.—Male, aged 8. Influenza, severe onset.

4



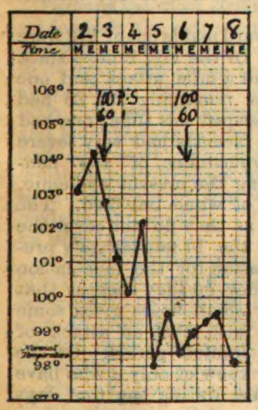
CASE 4.—Male, aged 38. Influenzal broncho-pneumonia.

9



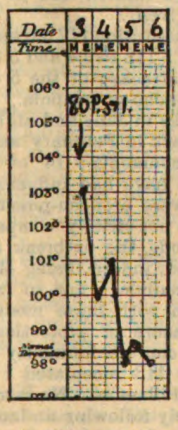
CASE 9.—Male, aged 50. Very severe confluent broncho-pneumonia.

5



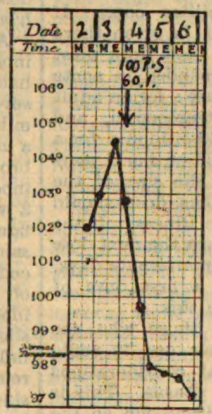
CASE 5.—Male, aged 28. Influenzal broncho-pneumonia.

6



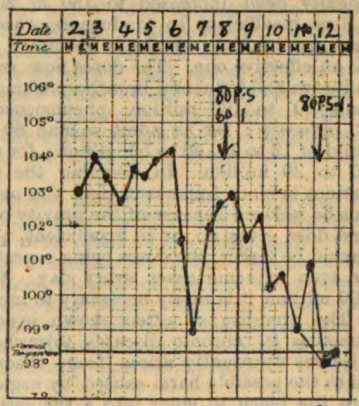
CASE 6.—Male, aged 21. Influenzal broncho-pneumonia.

7



CASE 7.—Male, aged 28. Influenzal broncho-pneumonia.

10



CASE 10.—Male, aged 28. Very severe confluent broncho-pneumonia.

cyanosis. Each injection was followed by a fall in temperature, and after the third the normal temperature persisted. Two more injections were given during convalescence. This patient also had left femoral thrombosis during convalescence. These are the only two patients in whom I have seen this complication.

CASE 10.—Man aged 28. This patient was not seen until the eighth day, when he appeared to be dying. He had extensive confluent broncho-pneumonia, with a respiration-rate of 52. He was lying in a condition of stupor, with weak flickering pulse. He was injected with 80 million pneumococci and streptococci and 50 million influenza bacilli after some hesitation as to whether it was worth while. From that time he steadily improved and two days later respirations were 26. A second inoculation was made on the twelfth day and temperature became normal.

These patients were as desperate as any I have seen, and I feel sure would not have recovered if vaccine had not been used.

The youngest patient injected was a baby of 12 months. Her illness began with convulsions. She was seen by me towards the end of the second day and then had well-marked broncho-pneumonia. An injection of 15 million of each organism was given. The child was then listless, peevish, and obviously ill. When seen 38 hours later she was sitting up and playing.

The oldest patients were a husband and wife, aged 69 and 68 respectively, both bad subjects, with severe broncho-pneumonia. 80 million of each organism were given on the first and second days respectively and each patient made a good response. Several children of 10 and 12 years have been injected with doses of 50 million and children of 3 and 4 years with 20 million. In all cases with good results.

Results of Curative Vaccination.

In no case have I seen any bad result from the use of vaccine in these doses when used early in the disease. If it may be argued that vaccine has no curative action in acute diseases a study of these cases will show that at least it does no harm. A constant feature has been the drop in temperature following an injection. This if standing alone might mean little, or if associated with collapse would be a bad sign, but in these cases the fall of temperature is associated with general improvement, the aspect of the patient is better, the pulse is slower. In acute lobar pneumonia the respirations are slowed *pari passu* with the temperature and pulse. In influenzal broncho-pneumonia, if the respirations are rapid they are slowed with the fall of temperature, but in the serious cyanotic cases with slow respirations the rate is increased. In Case 8, for instance, during the critical days the respirations were 20 to 30, but after the temperature became normal the rate increased to 48. At first the respiratory centre is depressed, but with improvement comes stimulation of the centre before it returns to normal. The results obtained in influenzal broncho-pneumonia are similar to the results obtained for several years in acute lobar pneumonia and other types of broncho-pneumonia. The charts given here have a close resemblance to those published in the article on vaccines in acute pneumonia already referred to. Such results cannot be explained otherwise than by assuming that the injection of an adequate dose of vaccine causes a satisfactory immunising response.

The Question of Dosage.

When I first used vaccines in these diseases such small doses as 5 million were given. Although occasionally good results were obtained they were uncertain. With further experience the doses became larger and the results better. In acute pneumonia, when 100 million pneumococci have not given a satisfactory response the dose has occasionally been increased to 150 or 200 million cocci. If a dose insufficient to produce improvement is given there may not be time to give a second. The first dose must be an effective one. The doses now recommended in acute influenza and influenzal broncho-pneumonia are: for an adult man 80 to 100 million pneumococci, streptococci, and *B. influenzæ*; for an adult woman 60 to 80 million; for a child of 12 to 14, 40 to 50 million; for a child of 2 or 3 years 10 to 20 million. In deciding the dose the size of the patient is more important than the age. The dose should not be reduced because of the gravity of the illness. If the first dose gives no, or an insufficient, response the next dose should be larger, the doses being repeated on alternate days, or even in some cases every day. With a first dose of 100 million it is rarely necessary to increase this.

The timidity so often shown even by those who use vaccines in chronic diseases towards their use in acute diseases apparently arises from theoretical considerations as to the possible harm caused by negative phases. This is not the place to enter into a theoretical discussion on the mode of action of vaccines in acute diseases. My attitude for the moment is the pragmatist's, "It is true because it works." But it may be pointed out that the doctrine of the negative phase was worked out in patients suffering from chronic localised diseases. The conditions existing in healthy persons and in patients with acute disease are very different and not comparable.

Those accustomed to vaccine therapy know that in the treatment of chronic localised diseases—chronic arthritis, mucous colitis, chronic bronchitis and asthma—considerable reactions may be produced by quite small doses, and great care is necessary in increasing the doses. The patient appears to be "sensitised" in a different manner to those suffering from acute disease. Again, a dose of ·000,0001 c.cm. tuberculin may cause a smart reaction in a case of chronic localised tuberculosis, but would have no effect in a case of advanced phthisis or acute caseous broncho pneumonia. One possible explanation may lie in the very different amount of infection in the two cases. A dose of 100 million pneumococci is very small as compared with the inconceivable number of cocci in the body of a patient suffering from acute pneumonia, but becomes appreciable when compared with the number present in a case of chronic otitis media.

Prophylactic Vaccination.

These considerations have a bearing on the use of vaccines for prophylaxis. Doses which seem inadequate are being recommended apparently from the fear of a period of increased susceptibility following upon inoculation, or of the possible danger of inoculating a patient during the incubation stage. Within certain limits the period of immunity depends upon the size of the dose inoculated, the limits being set not so much by the actual quantity of vaccine used as by the amount of antigen which the tissues can set free from it. With typhoid, doses of 1000 million and 2000 million are necessary to produce immunity lasting a reasonable time. With the pneumococcus Lister advises three inoculations at seven days' interval, each dose consisting of 6000 million cocci of each of several groups. He found that injection of very large doses was followed by only slight reactions. Sir A. E. Wright found that doses up to 40,000 million pneumococci produced nothing more than a very slight constitutional disturbance and a very small rise of temperature. Cole and his fellow-workers agree with these observations. We have no similar data with regard to influenza bacilli and streptococci. But doses of 300 up to 1000 million of these have been given for treatment. Further, as regards the possible danger of inoculating a patient during the incubation stage, Wright[3] has shown that 2500 men inoculated with doses up to 1000 million pneumococci had an incidence rate during the four days following inoculation only one-third that of 750 uninoculated controls—in other words, vaccine therapy is highly successful when applied during the incubation stage. I consider the incubation stage of all times the best to inject for treatment if we could discover it in the individual.

Prophylactic injections have been given to 230 persons, 100 million of streptococci and pneumococci and 50 million *B. influenzæ* being used as a first dose, and after a week double these doses to 90, but as there is no good reason for reducing the number of influenza bacilli the last 140 have had equal numbers of each organism. In some cases a third dose of 400 million and in a few a fourth of 800 million has been given.

At one institution 117 nurses and ward maids out of 170 were inoculated; 112 twice and 5 once. Of the 112, 2 have since had mild attacks; of the 5 one had a mild attack and one severe broncho-pneumonia. Of the remaining 53, 25 had mild attacks in June and all have escaped this time; one had a mild attack in February and has recently had very severe broncho-pneumonia; 14 of the remainder of the non-inoculated have had influenza during the present epidemic, 2 with severe broncho-pneumonia, of whom one died. The figures are not strictly comparable as they do not cover the same periods, the outbreak among the 14 immediately preceding, and, indeed, being the occasion for the inoculation of, the remainder; but so far as they go they suggest that inoculation with these moderately small doses gives some slight measure of protection, and also that an attack of influenza confers immunity for a limited period. Of the remaining 113 inoculated I so far know of only 2 who have since had influenza. No case fell sick during the four days immediately following an inoculation.

SOME OBSERVATIONS ON THE RECENT INFLUENZA EPIDEMIC

AT A BASE HOSPITAL IN FRANCE.

BY D. T. HARRIS, M.B., CH.B. MANCH., M.B., B.S. LOND.,
CAPTAIN, R.A.M.C.; RESEARCH PATHOLOGIST TO THE CHRISTIE HOSPITAL, AND LECTURER IN PHYSIOLOGY AT THE UNIVERSITY, MANCHESTER.

I.—*An "Intensive" Culture Medium for the Isolation and Growth of Pfeiffer's Bacillus.*

As the growth of *B. influenzæ* is better in association with staphylococcus than in pure culture, it appeared that possibly the basis of the symbiosis was a pabulum created by a proteolytic ferment generated by the latter organism, containing all the split-products of protein in all stages of cleavage. If this were true, then *B. influenzæ* would be expected to grow abundantly in the presence of an active tryptic ferment in the medium. The simple method of trypsinising whole blood and adding it to ordinary nutrient agar yielded a prolific growth of the organism. Strict asepsis must be observed in the technique, as subsequent sterilisation is inadmissible, the whole point of the method being to avoid the inactivation of the ferment.

A simple method adopted was the following:—

Into a 10 c.cm. syringe containing 3 c.cm. of citrated (1 per cent.) physiological saline, 5 c.cm. of rabbit's blood is drawn; this is quickly added to a mixture of 5 c.cm. citrated saline with 2 c.cm. liq. trypsinæ co. contained in a test-tube. The whole is mixed and placed in the incubator for one hour to start the proteolysis of the serum-albumin and globulin. Meanwhile, 100 c.cm. of nutrient agar (acidity + 10) in a 200 c.cm. flask is cooled down to 46° C. in a water-bath. The trypsin-blood, previously placed for a minute or two in the bath, is added to the agar at 46° C. Ten plates are quickly poured, and afterwards stored in the ice-chest until required.

The red blood cells are not too far altered by this treatment to preclude facility in making observations on the hæmolytic power of organisms, provided that growth has not exceeded 24 hours in the incubator, for in the latter case the red cells would be completely digested by the ferment.

This medium may be used with advantage for the growth of other delicate organisms—e.g., the gonococcus.

Note on oxygen supply.—For the growth of obligatory aerobes it has been shown that the essential constituent in blood media is the hæmoglobin. Is the function of the Hb to provide a readily available supply of oxygen? To determine this point, an agar medium was made in which neutralisation was effected by the chemical equivalent of sodium peroxide in place of caustic soda. The employment of this peroxide is confronted with technical difficulties. Since prolific growth on potato may be due to the presence of oxidases and peroxidases, one may possibly find that the addition of minute quantities of certain colloidal metals will be easier to incorporate in media for the same purpose. The call for oxygen by these obligatory aerobes is probably due to the necessity for the rapid oxidation of products like lactic acid, which inhibit growth.

II.—*The Extreme Prostration and the Involvement of the Suprarenal Capsule.*

Perhaps the most striking feature of the present influenza epidemic is the extreme prostration. Suddenly the patient appears to lose his physiological resistance completely, and in 24 hours the pulse becomes almost imperceptible. This atonia drew attention to the condition of the suprarenal body. In the first autopsy (in which the heart, spleen liver, and kidneys were normal) the left adrenal was soft, diffluent, and congested. On examining histologically it revealed multiple hæmorrhages in the medulla extending into the zona reticulata of the cortex and œdema of the cells of medulla and cortex. (Further examinations were held up by routine work.)

It is possible that adrenalin in small doses, repeated four-hourly, might prove useful during this period of marked asthenia, to be followed in convalescence by the administration of suprarenal capsules until repair is complete. The arterial tension might be used as an index for the control of treatment.

III.—*An Organism Resembling* B. pestis *in Appearance.*

Introduction.—Cultural examination of the aseptically obtained lung-juice from a case of "influenza" eight hours after death gave an organism resembling *B. pestis* in appearance. To eliminate the possibility of it being one of the many types of organism found post mortem the lung-juice was aspirated immediately after death (within a quarter of an hour) in the second case. From these two cases—both German prisoners of war—similar colonies grew out.

It was not until a fortnight later that the same organism was isolated from the throats of "carriers"; these were again two German prisoners of war, who had been sent in for bacteriological diagnosis of diphtheria and were found to be negative. [It may be of interest to record here that in two cases of death from this "influenza" the Klebs-Löffler bacillus was recovered from the lung. Aphonia had been a symptom in one of these cases.] The characters of the plague-like organism will now be given:—

Morphology.—The organism is remarkably pleomorphic. The type found in parent culture is a short plump bacillus. Its breadth ranges 1–2 μ; its length varies, mostly 2–3 μ; here and there longer forms may be met with up to 4 or 5 μ.

Staining characters.—The most striking characteristic is the marked polar staining. The organism stains well with aniline dyes. It does not retain the stain in Gram's method.

Cultural characters.—Isolation and growth are difficult in comparison with *B. pestis*. The organism was first isolated from the top, shallow, partially desiccated film of a serum slope. This suggested that it grew best on a hypertonic neutral medium; subcultures were therefore made on 2 per cent. salt neutral agar plates.

The parent growth on serum appears as a white colony about 1–2 mm. diameter in 24 hours. Subculture on gelatin proved a failure on two occasions. Subculture on salt-agar yields dense cream-coloured circumvallate colonies up to 3 mm. diameter in 24 hours; these show chains of bacilli and pear-shaped involution forms. (Hankin describes similar forms for *B. pestis* grown under the same conditions.)

Pathogenicity.—This has not been satisfactorily investigated. Only subcultures on salt-agar have been tested, and these were found to be avirulent: hypodermic injection of a rat caused 3 or 4 days' illness with subsequent recovery, whereas intraperitoneal inoculation of a guinea-pig only served to sharpen the appetite.

Further investigation with early cultures on a less attenuating medium is desirable.

Conclusion.—The organism thus agrees with *B. pestis* in morphology and staining characters, but isolation and growth are far more difficult than with *B. pestis*. Its virulence, if any, may depend on the concomitant action of some other organism—e.g., *Streptococcus brevis* or *viridans*—similar to what is suggested for Pfeiffer's bacillus.

I wish to express my thanks for the interest taken by the Assistant Adviser in Pathology for the Calais area (Captain E. L. Horsburgh, R.A.M.C.) in the verification of my observations.

SOME CLINICAL ASPECTS OF LONG-STANDING PULMONARY TUBERCULOSIS.

BY CECIL D. WOOD, M.B., B.CH. OXON., M.R.C.P. LOND.,
ASSISTANT MEDICAL OFFICER, BROMPTON HOSPITAL SANATORIUM, FRIMLEY.

THE last decade has seen a wide dissemination of knowledge with regard to pulmonary tuberculosis among the medical profession. Thanks more to individual apostles than to the teaching of the medical schools, practitioners now think far more frequently of tubercle in patients showing pleurisy, hæmoptysis, or intractable cough, and realise that in the great majority of cases these events signify pulmonary invasion, and in most cases metastasis from a previous lymph-gland focus. Meanwhile the books and journals, English and foreign, shower on their readers methods devised to facilitate a yet earlier diagnosis.

While, therefore, current medical literature abounds in appeals for the early diagnosis of *early* tubercle, it may seem odd that one should have to plead for the early diagnosis of *late* tubercle. But the fact remains that one sees case after case in sanatoria, in which pleurisy or hæmoptysis occurred seven or eight years ago, after which the patient was lost sight of from a medical point of view, and consequently was not thought of as a possible case of phthisis when he applied to a doctor after some years for the relief of further symptoms.

So benign is the course of phthisis, that many of these patients whose treatment only lasted a week or two at the time of the original manifestation, have maintained reasonable

health and working capacity over several years without attaining pathological healing. This was very obvious in the review of recruits for the Army, where in so many cases men were accepted not as cases of obsolescent tubercle fit for service, but simply without any recognition that they were in any way abnormal. Many have stood military life well; many, alas, have gone under.

Non-recognition of Cases and its Results.

That some of these cases should have escaped recognition need cause one no surprise; there are many conditions much more easily observed. In the absence of careful history-taking, and with a frequent absence or denial of sputum on the part of the patient, a cursory chest examination on the traditional lines may not rouse suspicion, since compensatory changes in the chest have a marvellous power of masking signs, especially in men, in whom the round, silent, emphysematous chest is commoner than in women.

The chest may be reasonably resonant, except perhaps at the extreme apices, and there may be no adventitious sounds of any kinds. The breath sounds may be weak or slightly harsh in quality, but more or less equally so all over. But while in some cases the physique may be good, careful inspection of the chest is generally enough to provide the necessary clue. Shelving apices and local rib deformities and asymmetries, supraclavicular hollows, muscular wasting about the shoulder-girdle, heart displacements, localised respiratory movements, and the use of extraordinary accessory muscles of respiration; some or all of these will help to indicate the damage that has been done.

The result of these cases being missed is that many patients who are really old chronic phthisical subjects, are not recognised as such when they first begin to feel run down, and too often it is only when they have gone on to breakdown, and their chests are a mass of squeaks and crackles that they are diagnosed at all. The fortunate few who find their way to a sanatorium when their initial manifestation of pulmonary invasion occurs, learn automatically that they have consumption. They are marked down as tuberculous; and that greatly to their advantage, since a subsequent toxæmic bout is less likely to be passed over as influenza, and the past history is much more likely to be brought to the notice of the medical attendant.

But even assuming that the old obscure fibroid cases are lucky, and previous to breakdown get swept into the net of the tuberculosis institutions, even so, they are not always recognised at once for what they are. Charts of their chest condition are handed about from one place to another, with perhaps a few strokes across the clavicles and "no adv. sounds," just as though they were cases of early pulmonary deposit. This is most unfortunate, because their difficulties and their treatment are not entirely the same as those of the early case. Most of the ordinary canons of sanatorium routine are common to both. Both must have rest until toxæmia has subsided. But the old fibroid cases have a disability which the early cases do not present, and I should prefer to call it their *mechanical disability*.

Oxygen-want.

Generally speaking, they have achieved all the compensation of which they are capable, and their response to exertion varies according to the extent of the damage to their respiratory apparatus. The early case has no marked difficulty in getting his blood oxygenated. If he is at all dyspnœic it is generally a toxic manifestation which disappears with his toxæmia. But the old chronic remains dyspnœic on exertion when quite free from toxæmia, and his disability is reflected in his colour oftener than the text-books would lead one to suppose. Unfortunately, most doctors only recognise a person as "cyanotic" when he is (in the modern sense of the word) quite blue, as in congenital heart disease or some cases of "idiopathic" emphysema. But this intense blue appearance represents more than pure oxygen-want. It is oxygen-want plus venous congestion, and the cyanosis of old tubercle and other conditions is not always a striking blue, but more often an ashen, livid, or leaden tint. It may be that the blue colour occurs where there is some degree of right heart congestion; in many of these chronic cases we certainly get some objective evidence of the heart working under strain, but unfortunately little work has been done as yet, which enables one to estimate the amount of the mechanical disability directly attributable to the myocardium. The main thing to recognise is, that when a tuberculous person is cyanosed or livid, his blood is not properly oxygenated for the degree of activity in which he has at that moment engaged. He may not complain of dyspnœa except on strenuous exertion, though his respiration may be increased both in rate and depth. The range of automatic compensation is wide. I have even seen patients engage in a short period of obvious forced breathing at the sight of a hill, thought quite unconscious of the fact!

But the question is, To what extent does this slight chronic oxygen-want matter? More, it may be, than is usually supposed. Apart from any theoretical disadvantage to viscera already past their prime, there is reason to think that it may be a direct cause of physical and mental ill-health. Many chronic tuberculous subjects who show none of the ordinary signs of tuberculous toxæmia, who keep an afebrile chart, and whose signs are quiet nevertheless complain of vague malaise, with many queer subjective symptoms, some of sympathetic type; sinking feelings, feelings of constriction, palpitation, insomnia, headache, nausea, depression, and nervousness, and other sensations reducing both their comfort and their working capacity. One cannot attribute all of these to the imagination or to indiscretions in diet. It is naturally most difficult to place them accurately, but perhaps it will be possible eventually to separate the syndrome of "anoxæmia" from that of tuberculous toxæmia, when the effects of slight oxygen-want over long periods are more definitely understood. This is certainly one of the directions in which increased coöperation is required between the physiologist and the clinician.

Relation to Classification and Treatment.

In handing on these cases to the care of another, it is plainly going to help him very little in assessing their capacity or recording their progress, to know that they are "ambulant afebrile," or that they come into Class 2 or 3 of Turban's grouping. Nor does Philip's valuable method enable one to record shortly *all* the essential factors. But with a small modification it would do so. In any case of pulmonary tuberculosis one wants to record shortly: (1) extent of lesions; (2) degree of toxæmia; and (3) mechanical disability; and this might well be done by the combination of the letters L T M, numbered from 0 to 3. Thus cases like those under consideration would often be $L_3T_0M_1$—extensive lesions, no toxæmia, slight mechanical disability. In so far as shorthand notes of cases are of value, such a method would cover the essential factors of pulmonary tuberculosis in all its stages. And in actual practice such a note certainly makes for careful observation of patients, by continually drawing one's attention to fundamentals. It is especially in institutions that patients are so liable to go automatically through a routine, unless anything gross happens to call attention to their particular needs.

Again, in special treatments, like artificial pneumothorax, it is most essential to consider all the factors involved. It is of doubtful advantage to an old fibroid case (except as a life-saving operation) to flatten out his foci by collapse therapy, and at the same time to leave him with too little lung to carry on his occupation with comfort, and with an overworked heart handicapped by the embarrassment of a displaced mediastinum. And the same care is wanted in fixing the limits of activity for these chronic cases where surgical treatment is not undertaken. They will not generally benefit by being taken past the stage of exercise represented by light gardening, nor is there any justification for making them short of breath

The country is alive with schemes, some in an early stage, some already in working, for dealing with the tuberculous patients discharged improved from sanatoria. How are these old chronic fibroid cases going to fare? Their working capacity is often great, and their expectation of life indefinite. They can do a relatively large quantity of work, assuming it is work of the right kind and within their respiratory capacity, but they are not capable of sudden great exertion, and are most comfortable on a fairly sedentary job. It follows that in the laudable desire to get them open-air conditions we must not overlook their limitations. If we are going to send them to open-air colonies we must make provision for sedentary occupations, many of which are compatible with open-air conditions. They will certainly live longer and do more useful work under the light physical strain of sedentary employment than they would by going blue in the effort to get through the average day on a farm.

A CASE OF

BENCE-JONES'S ALBUMOSURIA WITH LYMPHOCYTIC LEUCOCYTHÆMIA.

BY HENRY L. HEIMANN, B.A. CAPE,
AND
C. BAWDEN WILSON, B.A. CANTAB.
With Note by
H. BATTY SHAW, M.D., F.R.C.P. LOND., F.R.C.S. ENG.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

Note by Dr. BATTY SHAW.—The following case appears to be of special interest because of the association of leucocythæmia with Bence-Jones's albumosuria; presumably the marrow has shared with other tissues in producing the picture of leucocythæmia. If Bence-Jones's albumosuria were expressive of a pathological function of the marrow, then it should be more common in leucocythæmia, especially in the myelocytic form. It has not been my experience to meet with this coincidence of leucocythæmia and Bence-Jones's albumosuria before, nor is it referred to much in the literature on the subject. I can only therefore conclude that the association is purely an example of coincidence, or would be more frequently observed if greater care were taken in the examination of the urine in cases of leucocythæmia as was happily taken by Mr. Heimann and Mr. Wilson in this case.

The patient, a married woman aged 39, was admitted to University College Hospital, London, on July 22nd, 1918, under the care of Dr. Batty Shaw.

There was a history of "albuminuria," shortness of breath, and cough for 14 days, with blood-stained expectoration. She stated that in childhood she had had scarlet fever, measles, and whooping-cough, whilst for the last ten years she had suffered from anæmia. In August, 1917, her legs began to swell, but returned to their normal size on resting; she was unable to resume her occupation without the same condition recurring.

There was no swelling of the legs when she entered hospital; her complexion was waxy in colour and she looked wasted. The anterior abdominal wall was lax and there was a ventral hernia; the liver was palpable to a distance of three finger-breadths below the costal margin and an enlarged spleen extended two inches below the subcostal plane in the direction of the umbilicus. The heart was enlarged; there was a well-marked "blowing" systolic murmur in the mitral area, and this was conducted into the axilla. Nothing abnormal was found in the chest. No albumin was found in the urine, but on heating a flocculent precipitate appeared which largely disappeared on boiling.

Urine examination.—A detailed examination of the urine was made (H. L. H. and C. B. W.).

A 24-hours' specimen was filtered. The filtrate was clear and measured 1275 c.cm. in volume; the reaction was acid and the specific gravity was 1018.

A test-tube of urine was heated in a water-bath, and a slight precipitate appeared at 56° C., and on gradually raising the temperature it became heavier by increments up to 62° C., after which there appeared to be no more precipitation. The precipitate was filtered off and the filtrate heated. No more precipitation occurred, so it was concluded that precipitation was complete at 62° C.

On heating the urine to boiling point all the precipitate first formed redissolved, with the exception of a trace which disappeared on the addition of a few drops of acetic acid.

It was apparent that we were dealing with Bence-Jones's albumose, and the following confirmatory tests were made:—

To a test-tube of the specimen caustic soda and a few drops of copper sulphate were added, and a deep rose-red colour developed in the cold (biuret test).

Other tests for proteins:—A. Colour reactions: (1) Xantho-proteic, positive; (2) Millon's reagent, positive; (3) Molisch's test; positive; (4) the sulphur reaction was slight.

B. Precipitation reactions: (1) Ammonium sulphate, precipitate; (2) HCl (strong), precipitate; (3) ferric chloride, precipitate (solution in excess); (4) alcohol, precipitate; (5) picric acid, precipitate; (6) mercuric chloride, negative; (7) trichloracetic, negative.

All the above tests were confirmed in a solution of the purified albumose.

Further experiments were made with a specimen of urine and a saturated solution of ammonium sulphate.

It was found that on adding 8 c.cm. of ammonium sulphate solution to 10 c.cm. of urine an opalescence appeared. This was filtered off and a clear solution obtained. It was found that the filtrate gave no precipitate on adding more ammonium sulphate until a further 4·7 c.cm. of saturated solution had been added.

This process was repeated, and a series of definite precipitates was obtained for definite concentration of ammonium sulphate in solution. All these precipitates gave the biuret reaction for albumose.

This phenomenon, combined with the different increments obtained by coagulation, suggests that Bence-Jones's albumose is a complex of a number of albumoses.

Estimation of the contents of the urine was made by us, the patient being on a light fish and milk diet.

Total sulphates	1·8 g. H_2SO_4	Urea N	9·27 g.	10·29 g.
Total N (Kjeldahl)	11·7 g.	Creatinine N	0·15 g.	
Albumose N	1·09 g.	Ammonia N	0·61 g.	
Unestimated N	0·32 g.	Uric acid N	0·26 g.	

This leaves 1·41 g. of N which is made up of albumose N, and other N products which we were unable to estimate.

Estimation of N in albumose.—It was found that mere precipitation by heat of the product and washing subsequently was unable to purify it.

Therefore 25 c.cm. of urine were taken; the albumose was coagulated and filtered off. It was then redissolved in boiling water and the precipitate obtained by cooling. This was thoroughly washed until no urea reaction was given by filtrate. No albumose was lost by this method, as was ascertained by testing the various filtrates.

The precipitate was then dried and weighed. The total albumose excreted per diem was found to be 35·7 g. The nitrogen content of albumose was found to be equivalent to 1·09 g. per diem. The albumose therefore contains 3 per cent. of nitrogen. We see the unestimated N amounted to 0·32 g. per diem.

A catheter specimen of urine was examined by the bacteriologist for organisms, and streptococci were found in large numbers and in pure culture. The strain was very virulent to rabbits. No casts were found in the urine.

Blood examination by F. H. Teale, M.D. Lond., F.R.C.P., clinical pathologist to University College Hospital:—

Wassermann reaction negative.

Total red cells, 2,860,000 per c.mm.; hæmoglobin, 59 per cent.; colour index, 0·9. Average size of red cells was increased. Numerous microcytes and macrocytes were present. There were a few normoblasts and gigantoblasts. There were poikilocytosis and vacuolation.

Total white cells, 8000 per c.mm.; lymphocytes, 63 per cent.; large lymphocytes, 8 per cent.; hyaline cells, 1 per cent.; polymorphonuclear cells, 27 per cent.; polymorpho-oxyphile cells, 0; myelocytes, 1 per cent.

The patient was under observation until August 16th, 1918, when she left the hospital. During that time she always had a slight evening temperature (average 99·6° F.). Her appetite was good, and she complained of always being hungry, whereas her weight, which was 6 st. 9 lb. on entering, never rose above 6 st. 11 lb. The urine was examined daily, and showed on each occasion the characteristics described above. We were unable to account for the presence of the streptococci in the urine, and she showed no signs of harbouring virulent pyogenic organisms in her bladder or upper urinary passages.

No deformities were found in the spine, nor were there any painful areas on any of the long bones. No enlargement of the lymph glands could be detected, and no metaplastic nodules were felt in any part of the body.

The condition of her heart had improved, and the cough had disappeared when the patient was discharged.

Diagnosis.—The outstanding points in the case seem to be the presence of the albumose in the urine, with a relative and total increase of small lymphocytes in the blood, and the absence of any signs of malignant growths. F. Parkes Weber and Ledingham describe five conditions of myeloma—i.e., lymphocytic, myeloblastic, myelocytic, erythroblastic, and plasmocytic.[1] F. G. Hopkins and H. Savory state[2] that this proteosuria may occur in three pathological conditions, myelomatosis, lymphoid hyperplasia of bone marrow and osteomalacia. We are inclined to regard the lymphocytic myeloma of the former observers as identical with the lymphoid hyperplasia of the bone marrow of the latter observers, and we believe the case described is one of this type, and gives the clinical picture according to the blood count of lymphocytic leucocythæmia. The enlargement of the liver and spleen also points to a hæmopoietic disease.

The secondary points of interest in this case were the heart disease, exemplified by the enlargement, the murmur, and the dropsy in the legs, together with the presence of streptococci in the urine. It is tempting to ascribe the heart lesion to an endocarditis of streptococcal origin, and to speculate whether a pyogenic organism of this type can affect the bone marrow and lead to the production of a lymphoid hyperplasia. We are convinced that this was a case of albumosuria from the beginning, and that the albumin reported in the urine earlier in the disease was really the proteose we found. It is possible, however, that the patient had true albuminuria during the periods of dropsy. We were unable to examine the urine and blood of her three children, who were at work and apparently healthy.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SIX CASES OF PURULENT BRONCHO-PNEUMONIA ASSOCIATED WITH THE MENINGOCOCCUS.

BY J. A. GLOVER, M.D. CAMB., D.P.H.,
CAPTAIN, R.A.M.C.

DURING the examination of the contacts of a case of cerebro-spinal meningitis which occurred recently at the 4th London General Hospital, the following interesting facts were brought to light:—

The patient C., who subsequently developed cerebro-spinal fever, was admitted to hospital on Sept. 28th from Egypt with a long history of malaria and marked wasting. On Oct. 12th he was moved into another ward and placed in the next bed to a man, H. H. was a convalescent and one of the three survivors of a party of six men, all of whom had had severe purulent broncho-pneumonia and whose history will be dealt with later. H. had still a persistent cough.

Owing to the fireplace the beds of H. and C. were close together, although the ward was not crowded.

On Oct. 20th, after eight days of this close neighbourship, C. began vomiting and later developed other signs of meningitis.

On Oct. 24th, he being desperately ill, was lumbar punctured by me, turbid fluid with plenty of meningococci was obtained, and he has made a splendid recovery with antimeningococcus serum prepared for the Medical Research Committee, only two doses of the pooled I.–II. serum being required. The meningococcus in his naso-pharynx was Type I., that from the cerebro-spinal fluid not being grown.

Owing to the length of time C. had been in hospital it was probable that he had been infected there, and hearing of H.'s history of purulent bronchitis and persistent cough I took several swabs of him, all of which yielded a nearly pure culture of Type I. meningococcus.

The profuse growth from H.'s naso-pharynx contrasted strongly with the slight growth obtained from C.'s, from which the meningococcus was only recovered with difficulty after many swabs.

None of the other patients in C.'s ward was a carrier and the only staff contact who was positive was a sister who carried Type II., and who therefore obviously had neither infected nor been infected by either H. or C.

With the kind assistance of Dr. T. H. Jamieson I learnt, as stated above, that H. was one of the three survivors of a party of six patients transferred from Holborn Military Hospital, Mitcham, on Sept. 21st, all of whom had developed severe purulent broncho-pneumonia. Following up the other two survivors, I found that N., a great friend of H., but in another ward and on another floor, was also a "pure plate" carrier of Type I., and that the third survivor, J., who had been transferred to a convalescent hospital, was also carrying an almost pure culture of Type I.

All six of this party had been in hospital in Malta suffering from malaria acquired in Salonika. On August 29th they left there by hospital ship and arrived at Marseilles on Sept. 2nd, where they were 10 days under canvas in a general hospital. This they left on Friday, Sept. 13th, and after three days in a hospital train across France, crossed the channel via Southampton and arrived at Mitcham on Sept. 16th. On Sept. 18th all had high pyrexia, which in view of their history was considered malarial, and on Sept. 21st they were transferred to the Malaria Block of the 4th London General Hospital.

All now developed severe purulent broncho-pneumonia and three died, H., N., and J. only surviving after very dangerous illnesses.

Dr. Jamieson kindly gives me the following notes:—

In all cases there were marked dyspnœa and considerable cyanosis. In all cases the sputum was purulent and copious, and was *not* rusty or blood stained. Examination of the sputum showed pneumococci. In two cases there was diarrhœa, and in three albumin was present in the urine. The cause of death in each of the fatal cases was gradual cardiac failure. Two post-mortem examinations were done. Both showed broncho-pneumonia with quantities of purulent secretion in the bronchioles; in fact, the lungs, when cut into and held up, dripped pus. The sputum throughout had been noted as being very purulent. In none of the cases did any of the symptoms suggest meningitis.

We may now review our dates. H. was quite convalescent on Oct. 12th, when he was moved next to C. C.'s onset of cerebro-spinal fever was about Oct. 20th On Oct. 24th this was definitely diagnosed, and the same day H. was first swabbed and found to be a carrier. N. was found to be a carrier on Oct. 25th. J. on Oct. 26th, all nearly "pure plate" carriers of Type I. No other Type I. carriers were found among the contacts at either hospital.

In my opinion we may consider that C. was undoubtedly infected by H., and that in all probability the purulent broncho-pneumonia from which the six men suffered was due to a mixed infection of pneumococci or Pfeiffer's bacillus and Type I. meningococci. It was characterised by (1) high mortality, half the patients dying; (2) the extreme purulence and great abundance of the sputum; (3) the absence of rusty sputum or blood so common in the present epidemic of pneumonia. C.'s recovery was a dramatic proof of the potency of the Medical Research serum. Thirty-six hours after being apparently moribund he was demanding the morning paper, and he has only required two doses, although the first fluid showed many typical meningococci.

Efforts to isolate and agglutinate the meningococcus from H.'s sputum have failed, but it is to be remembered that this was only attempted more than a fortnight after convalescence was fully established.

LOCAL ANÆSTHESIA FOR EMPYEMAS.

BY C. W. MORRIS, M.B., B.S.DURH., M.R.C.S., L.R.C.P.,
TEMPORARY SURGEON COMMANDER, R.N.; CONSULTING ANÆSTHETIST, ROYAL NAVAL HOSPITAL, HASLAR;
AND
L. HORSLEY, M.R.C.S., L.R.C.P.,
TEMPORARY SURGEON LIEUTENANT, R.N.; ROYAL NAVAL HOSPITAL, HASLAR.

AT the present time when the influenza epidemic, with its sequela of pneumonia, is subsiding, and the virulence of the infection is lessening, a large number of the pneumonia cases, who in the earlier stages of the epidemic would have died, are developing empyemas. In view of the very serious condition of many of these patients the administration of a general anæsthetic for the removal of a rib is accompanied by great danger and likely to prove either fatal at the time of the operation or seriously to minimise the chances of recovery.

It is on account of these dangers that we have always employed local anæsthesia at the Royal Naval Hospital, Haslar, both before and during the present epidemic, and the experience gained in dealing with 150 cases, of which 85 occurred during the last six months, may prove of interest and use to those who are now faced with like cases.

We use a 0·5 per cent. solution of novocaine and sterile water, to which adrenalin chloride 1 in 1000 is added in the proportion of three drops to the fluid ounce, and the following is briefly our technique:—

The patient is placed in position on the table and the skin preparation made. Three inches of the rib over the site of the empyema are accurately outlined with a blue pencil, and the needle thrust perpendicularly through the skin at the posterior end of the marked area, injecting the solution at the same time, until the point touches the rib. The point is then directed down to the lower border and turned into the subcostal groove, and 5 c.cm. injected into the intercostal nerve.

Without withdrawing the needle the periosteum on the whole outer surface of this section of the rib, as far forward as can be reached through this puncture, is thoroughly infiltrated, beginning at the posterior end and working forward, paying especial attention to the two edges. The intercostal spaces above and below are injected and then the subcutaneous tissues and skin infiltrated. The needle is then withdrawn and inserted through the analgesic skin in the centre of the marked area, and the periosteum, intercostal spaces, and coverings of the rib infiltrated in a similar manner. One more puncture, again through the infiltrated skin, at the forward end of the marked portion of rib and the same process repeated will complete the infiltration. Should sufficiently long needles be used the whole area can be covered by two infiltrations, one at each end.

We find that to ensure the best results some 20 c.cm. must be injected at each of the three punctures, and in stout patients larger quantities will be necessary. If the vertical incision rather than that along the rib should be preferred, we carry out the same infiltration, with the addition that we extend

the injection through the second puncture into the skin and subcutaneous tissues well over the intercostal spaces above and below. The infiltration is easy to carry out and only takes a few minutes; the patient feels only the one prick of the needle. The operation can be started immediately it is finished. It is necessary to emphasise the importance of using the rib shears with the utmost care, as any wrenching will give rise to pain at the costo-sternal junction.

On opening the pleural cavity there may be some discomfort, especially should the patient have a fit of coughing, which is sometimes the case in large empyemas.

In nearly all of the 85 cases operated upon since May the patients were suffering not only from empyema but had signs of active pneumonia in both lungs, and many had a blood pressure of well below 100 mm. Hg. Notwithstanding their serious condition no patients were lost at the operation nor did their behaviour during it give rise to further anxiety.

We claim that local anæsthesia for these patients gives greater safety and increases the chance of ultimate recovery.

INFLUENZA AND BLACKWATER FEVER.

BY SAMUEL SAMUEL, M.B., CH.B. LEEDS, M.R.C.S.,
LATE CAPTAIN, R.A.M.C; HONORARY MEDICAL AND SURGICAL OFFICER, LEEDS JEWISH HOSPITAL.

MUCH has already been written in connexion with the present influenza epidemic, both in regard to its etiology and its complications. In the lay mind especially the present influenza has been looked upon by some individuals as a type of malaria, probably spread by the returning malarial soldier, and this, amongst other reasons, accounts, to a certain extent, for the great consumption of quinine, both as a prophylactic and as a curative drug.

The present influenza has been of a most virulent type, and the commonest of complications have been the various hæmorrhages which have included the various rashes, bleeding from certain organs—e.g., nose, uterus, stomach, lungs, &c. Though cases have occurred frequently where blood has appeared in the urine, it has chiefly been present when an acute nephritis has beeu a complication. I doubt, however, if many have experienced a case similar to the following, where the urine has appeared as blackwater, similar to what some of us who have seen active service in Macedonia have witnessed.

The patient, a male aged 45, previously quite well in health and never domiciled abroad, began on Monday, Nov. 25th, with typical influenza. He was treated with simple remedies such as spir. æther. nit. and simple alkalies, but no quinine was administered. His temperature began to subside on the third day, i.e., on the Wednesday. This same day he began to complain of violent colic in the epigastrium, which on the following day moved also to the flanks. Warm applications, simple warm-water enemata, and even small doses of morphia, had no effect in quieting the pain. On the Friday evening, whilst the pain was still severe, the patient passed quite an abnormally large quantity of urine as black as ink, with a reddish tinge showing just at the edge where the urine came in contact with the side of the chamber. An examination of the urine revealed the same features as are present in typical blackwater fever. On the Saturday morning the patient was seen in consultation with Lieutenant-Colonel G. W. Watson, who ordered tr. belladonnæ in 5 min. doses every three hours for the colic and warm applications to the flanks. The colic began to disappear almost with the second dose, and in the evening the patient was free from pain, though still passing the black urine. On the Sunday the black urine began to clear and to diminish in amount. The patient's conjunctivæ and skin then assumed a marked yellow tinge, which, however, disappeared gradually in the course of the next few days with the nightly dose of calomel gr. 1 and a morning seidlitz powder. Albumin and granular casts still persisted for about two days after the blackwater disappeared, when these also disappeared.

The patient to-day (Dec. 9th) is free from all symptoms, though weak and anæmic and earthy-looking. He is now allowed up for one hour a day. Just a week has now passed and there has so far been no recurrence of the blackwater, and the urine is quite clear and normal in all respects.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE.

A MEETING of this section was held on Dec. 13th, when Dr. E. W. GOODALL, Lt.-Col., R.A.M.C., delivered his Presidential Address on

Enteric Fever in Flanders in 1914–1915.

He said that enteric fever was prevalent in Belgium at or about the time war broke out and cases occurred in England during the autumn of 1914 among Belgian refugees. The rapid advance of the Germans and the flight of the inhabitants were likely to assist the spread of the disease, the more so if the nature of the invaded country be considered. Belgium, west of a line drawn through Antwerp and Brussels, is a plain, intersected with rivers, mostly canalised, the water in which can flow but very slowly. This plain is, in places, thickly populated and highly cultivated, and human excreta are largely used for the purpose of fertilisation. The water is usually derived from shallow wells. Further, the Belgians, as a defensive measure, flooded the country to the north-east of Dixmude, the effect of which was to accentuate the stagnation. When trench warfare began, in November, 1914, the trenches were consequently in a very insanitary condition. At this time, of the four armies engaged in Flanders, the British alone was protected adequately by antityphoid inoculation. He gave evidence to show that by the end of November, 1914, there was in the Flanders area a considerable number of cases of enteric in the Belgian, French, and German armies, and probably amongst Belgian civilians, and a comparatively small number in the British Army. The outbreak began to assume epidemic proportions soon after the armies settled down to trench warfare.

An account was then given of the Friends' Ambulance Unit. Nearly all the members belonged to the Society of Friends, many being professional men, so that whatever line of work was taken up there was no difficulty in finding, amongst themselves, expert organisers and advisers. Part of a large building just outside Ypres was given to them, and here the local headquarters of the unit and the hospital were set up. Besides the treatment of patients in hospital the medical officers of the unit carried on an extensive outdoor visiting practice amongst the remaining inhabitants of Ypres and the surrounding villages not occupied by the enemy, and the hospital had been recognised by the Ypres Committee of Safety as the Ypres Civil Hospital. The authorities of the British Army enlisted the services of this unit as a friendly link between themselves and the Belgian civil authorities to help them in their campaign against the epidemic. The area, not occupied by the enemy, affected by the epidemic was about 31 miles long and 12 miles broad, stretching from Nieuport on the north to Ploegsteert on the south. The epidemic probably spread rapidly towards the end of December, 1914.

With regard to the number of cases information was limited, but it was probably very considerable; there must have been about 4000 cases under treatment daily during January and February, 1915, in the French military hospitals in Dunkirk and its neighbourhood, and the number in the Belgian Army must also have been considerable. One thousand cases (Belgian civilians) passed through the hospitals of the unit at Ypres and Poperinghe, and about 1000 more came to the knowledge of the officers of the unit, which were treated elsewhere. The British Army furnished comparatively few cases—only 827 up to May 22nd, 1915.

Character of the Cases.

The disease differed in several points from the types the speaker had seen in England during the previous 25 years. 1. The fever ran a very irregular course, the oscillations being frequent and extreme, so that the chart at the height of the disease resembled in many cases that of pyæmia or phthisis. Temperatures of 104° to 105° F. were by no means uncommon. 2. A considerable number of the cases exhibited pronounced nervous symptoms, coma or semi-coma, or restlessness and delirium. These symptoms did not pass off as the general condition improved and the temperature fell. The comatose cases did worse than the others; in such cases death occurred without recovery of consciousness,

though the temperature fell. He attributed the mental state to the harassing conditions under which the patients had been living before they became ill. 3. Clinical evidence showed that the intestinal lesions were by no means entensive or severe. Death was due either to cardiac failure, probably caused by myocarditis, or to hypostatic pneumonia.

Cases which he saw later among French soldiers were less severe, and conformed to the type he had been used to seeing in England. This he accounted for by the fact that the patients were well fed, many had been inoculated, and a large proportion were cases of paratyphoid. As soon as laboratory methods of diagnosis were employed it was found that a considerable number of cases were paratyphoid. Of 43 cases at the Queen Alexandra Hospital, Dunkirk, in which the blood cultures were positive, 16 were typhoid, 22 were paratyphoid A, 3 were paratyphoid B, and 2 were paratyphoid, but whether A or B was not ascertained. If to these cases were added those in which the results of the blood serum tests were taken as clinching the diagnosis, there were 43 cases of typhoid, 32 of paratyphoid A, 12 of paratyphoid B, and 2 of paratyphoid, ? A or B, so that 52 per cent. were paratyphoid.

This proportion was very different from that found amongst the Belgian civilians admitted to the Hôpital Elisabeth at Poperinghe. Out of 308 cases in which the clinical diagnosis was supplemented by positive blood cultures or serum tests, 245 were typhoid, 62 were paratyphoid B, and only 1 was paratyphoid A—that is, 20 per cent. were paratyphoid. Several reasons were given which might account for this difference, one of which was the fact that of the 102 cases in the Queen Alexandra Hospital 29 per cent. had not been inoculated, whilst of the 454 cases admitted to the Hôpital Elisabeth 92 per cent. had not been inoculated. The presence in any particular area of more or fewer cases of the three varieties must also be taken into account. It was generally believed that paratyphoid A was introduced by carriers among the troops, as it was very rare in Europe before the war, and the figures given indicated that the Belgian civilians were not exposed to the infection of paratyphoid A, but that the French soldiers were.

Of the 435 cases admitted during the febrile period to the Poperinghe Hospital 93, or 21 per cent. died, whilst of 102 cases admitted to the hospital at Dunkirk 10, or 9·8 per cent., died. The Poperinghe cases were of all ages and both sexes, but with a majority of females; the Dunkirk cases were all males, mostly from 30 to 40 years of age. The fatality rates for typhoid and paratyphoid in the two hospitals were also different. For the Hôpital Elisabeth they were as follows: Typhoid, 9·7 per cent.; paratyphoid, 19·2 per cent. For the Queen Alexandra Hospital: Typhoid, 20·9; paratyphoid, 2·1 per cent.

Preventive Measures.

The measures employed against the epidemic were: (1) those for providing for the sick; and (2) those for protecting the healthy. 1. The medical departments of the several armies dealt with the soldiers, and the Friends' Ambulance Unit chiefly with the civilians. Hospital accommodation was provided for those who had to be so treated. 2. As regards the measures adopted for preventing the spread of the epidemic by protecting the healthy, the authorities acted quickly and energetically. They were such as are usually taken in epidemics of this nature—viz., (*a*) the removal and isolation of the sick in hospitals; (*b*) the cleansing and disinfection of premises; and (*c*) the provision of a safe water-supply. The inoculation of the civil inhabitants of the infected areas with antityphoid vaccine was made obligatory by the Belgian authorities, those who refused inoculation being liable to be expelled from the zone occupied by the Allied Armies and treated as refugees. Enteric fever was made notifiable, omission to notify being punishable by fine or imprisonment. The following table of statistics was given of inoculation of the Belgian civil population by the Ambulance Unit from Feb. 5th, 1915, to May 31st, 1916:—

1915.	First.	Second.	Percentages of second inoculations.	Total.
Feb. 5th to 28th ...	4,890 ...	2,649 ...	(54·1) ...	7,539
March 1st to 31st ...	4,942 ...	4,576 ...	(92·5) ...	9,518
April 1st to 30th ...	1,010 ...	972 ...	(96·2) ...	1,982
	10,842	8,197	(75·6)	19,039
To end of July, 1915	14,836	11,375	(76·6)	26,211
To end of May, 1916 (total inoculations)				26,700

By the middle of March the epidemic was on the wane as far as the French Army was concerned, and by the beginning of the summer it was at an end, not only in the armies, but amongst the civilians. Colonel Goodall attached more importance to the effects produced by the usual sanitary measures than to the inoculations, because the inoculations were against *B. typhosus* and not against *B. paratyphosus A* and *B*. Now that the enemy had been driven from Belgium the civilian inhabitants would be returning in large numbers, and every effort should be made to prevent a fresh outbreak.

SECTION OF OTOLOGY.

A MEETING of this section was held on Nov. 15th, under the presidency of Mr. HUGH JONES, of Liverpool.

Acute Osteomyelitis of Temporal Bone.

Mr. HERBERT TILLEY showed a boy who had made a remarkable recovery from Acute Osteomyelitis of the Right Temporal Bone. The patient was admitted to hospital on account of acute suppurative otorrhœa of six weeks' duration, associated with pain, pyrexia, sleeplessness, and malaise. The roofs of the antrum and tympanum were found at the operation to have been destroyed by disease, the dura was replaced by a mass of granulation tissue. The wound was left open and dressings applied. During the following month the soft tissues in the temporal and mastoid regions became swollen and œdematous. At the second operation the squamous and mastoid portions of the temporal bone were freely exposed, and were found to be so softened by inflammation that large portions could be scraped away and removed by forceps. During the long convalescence herniæ cerebri occurred on three occasions in the original mastoid wound. With the exception of a small sequestrum the patient was now well. Acute spreading osteomyelitis of the temporal bone Mr. Tilley regarded as rare, and most of the cases were fatal. Probably the very wide removal of inflamed bone accounted for the successful issue in this case.

Mr. W. STUART-LOW spoke of the value in such cases of a wound-protecting shield, which permitted efficient drainage and obviated pressure on the wound edges.

Mr. HUNTER TOD described three similar cases, two of which were fatal. Usually the pulse was not rapid nor the temperature very high. The only hope in such cases was early recognition and the removal of as wide an area of bone as possible. He regarded it as a blood infection.

Dr. D. R. PATERSON (Cardiff) commented on the extreme rarity of osteomyelitis of the temporal bone as contrasted with that of the frontal.

Symmetrical Lupus Erythematosus.—Epithelioma of Helix.

Mr. STUART-LOW exhibited a case of extensive Symmetrical Lupus Erythematosus. The patient, a man aged 45, had had the skin condition ever since he could remember, but it had extended more rapidly during the last few years, especially on the scalp. A portion of the tissue was pronounced by Dr. Wyatt Wingrave to be epithelioma grafted on to lupus erythematosus.

Dr. H. J. BANKS-DAVIS referred to a case of Epithelioma of the Helix which he removed in 1914 without operating on the glands, and in which the patient still remained free of recurrence.

Double Facial Paralysis due to Bilateral Tuberculous Mastoiditis.

Mr. W. M. MOLLISON showed a child, aged 13 months, who had been the subject of the above condition. Otorrhœa began at the age of 6 months, and had been considerable ever since. The mastoid swelling and change in the face were very recent. A profuse foul discharge came from both meati. At the operation the mastoid process was found to be soft and necrotic, and a series of sequestra were removed with a sharp spoon. Six days later the other mastoid was operated upon and a similar condition disclosed.

Mr. HUNTER TOD raised the question of the source of the milk for this child, as this condition was often found to be due to infected milk.

Mr. STUART-LOW remarked on the rarity of the occasions when tubercle bacilli could be found in the discharge.

Dr. PERRY G. GOLDSMITH (Canadian A.M.C.) thought the term tuberculous was often applied somewhat loosely to these cases. The rapidity of the healing in this case he regarded as against it being tuberculous.

The PRESIDENT related the cases of twins, 10 months old, who, two months before he saw them, had suffered from

double otorrhœa, and then developed enlarged cervical glands. The source of the milk supplied was declared to be quite beyond suspicion; the cow was kept by a gentleman farmer, who was said to have had his herd regularly tested with tuberculin. A portion of the granulation and discharge injected into a guinea-pig produced tuberculosis. The medical officer traced the milk to a tuberculous cow in this model dairy.

Dr. W. H. KELSON thought the rapid healing of this case formed no argument against the condition being tuberculous; he had had very quick recovery in such cases, even when the disease was extensive. But these cases were apt to break down periodically.

Necrosis of Internal Ear.—Radical Mastoid Operation.

Mr. MOLLISON also showed a man, aged 60, who had recovered from Necrosis of the Internal Ear, causing Sequestration of the Labyrinth. He had had pain in the left ear for years, and for three months had suffered from headache and vertigo. There was a large polypus in the left meatus, with foul otorrhœa. On exposing the antrum all anatomical landmarks were absent, and a kind of trench surrounded the labyrinth; the labyrinth was loose and could be brought away whole. The condition was not tuberculous.

Dr. PATERSON raised the point as to what degree of bone removal in order to deliver the sequestrum was justifiable. In some cases he had contented himself with loosening under an anæsthetic and then leaving it alone. He always feared a connexion with the carotid canal, or an attachment of the inner part of the sequestrum to the auditory nerve.

Mr. J. F. O'MALLEY asked whether syphilis could be excluded, as it was unusual for sepsis to isolate the labyrinth in this way.

Dr. DUNDAS GRANT showed two cases in which the radical mastoid operation was performed for Cholesteatoma, and in which the matrix had been preserved six months and 14 years respectively after the operation.

Several members congratulated Dr. Grant on the excellent results.

A Case of Medico-Military Interest.

Mr. O'MALLEY showed a case of Chronic Middle-ear Suppuration in a young soldier, for the purpose of raising important points of medico-military interest. This man's left ear had been constantly discharging for over two years. There was no history of disease in childhood, but he had had pain in the mastoid for eight months, worse at night. For the purposes of a pension award, was it justifiable to state that the trouble began not more than two years ago? Assuming him to have been in the Army over two years, should his condition be attributed to (*a*) military service; or as (*b*) only aggravated by it; or as (*c*) not affected by it? He also asked whether a radical mastoid operation was positively indicated.

Dr. GOLDSMITH said there was no objective evidence in regard to the man's pain, and the patient knew he would be paid if his deafness had been due to military service, or if it came on since the commencement of the war. The course of the case had not been that of acute middle-ear suppuration. His condition was aggravated, but not caused by, war service. Probably the trouble would not be removed except by operation. The pain he, the speaker, regarded as largely psychic.

Dr. DUNDAS GRANT said it was unfortunate that it had been necessary to take men into the Army without examining at all closely into the condition of their ears; many now in the Army would not have been there if such examinations had been made. The man should be given the benefit of the doubt, and his statement that he was well before he entered the Army should be accepted. As he had one good ear and calcareous changes in the other, his disability for pension purposes should be assessed at 20 to 30 per cent. If there were well-marked cholesteatomatous products he thought operation would be justifiable.

Mr. STUART-LOW said cases which had had a discharge at any time should have been cautioned not to bathe. He did not doubt that this man's condition had been chronic for years. He favoured operation.

Mr. ALEX. SHARPE, Colonel, R.A.M.C., thought this man's condition was contracted in the Service and was aggravated by it, but was not attributable to it. He would put the disability at 15 per cent.

Other cases were also shown.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE quarterly meeting of this Association was held at 11, Chandos-street, London, W., on Nov. 26th, under the chairmanship, owing to the absence of the President through illness, of Dr. DAVID G. THOMSON, ex-President.

The CHAIRMAN announced, with regret, the death of Dr. John B. Chapin, of New York, an honorary member, who for many years had been regarded as the Nestor of American psychiatry. He was in his 89th year, and had to his credit 50 years of service in hospitals for mental disorders. He retired in the summer of 1911. He also deplored the death of Dr. William Reid, who for more than 25 years was superintendent of the Aberdeen Royal Asylum, during which long term of office he saw the institution reconstructed at a cost of £50,000, largely owing to his own efforts. Also, the Association had to regret the death of Captain Frank Oswald Spensley, from pneumonia. He had served as senior assistant medical officer of the Darenth Industrial Colony, Dartford. Further deaths were those of Dr. T. S. Logan, of the Bucks Asylum, Stone, from influenza, Dr. A. Hume Griffith, medical superintendent of Lingfield Epileptic Colony, and Dr. T. Herbert, assistant medical officer of the York City Asylum.

Dr. R. PERCY SMITH reported on the work of the Lebanon Mental Hospital during the war under the care of its medical superintendent, Dr. Watson Smith. As the Turks recognised the institution as a religious or philanthropic one it had not been molested; they had supplied the hospital with food, despite the starvation going on around in Syria.—The Secretary was asked to write a letter of congratulation from the Association to Dr. Smith on his work under trying circumstances.

The meeting then discussed the recommendations from the Report of the English Lunacy Legislation Subcommittee. These were proposed by the chairman of the committee, Dr. H. WOLSELEY-LEWIS, seconded by the secretary of the committee, Dr. R. H. COLE, and duly approved.

The Interdependence of the Sympathetic and Central Nervous Systems.

Dr. DAVID ORR and Dr. R. G. ROWS submitted a contribution on this subject, supplemented by numerous illustrations. In the class of cord lesions which formed the subject of their previous work insuperable difficulties were encountered against accepting a "general intoxication" theory without qualification. Presumably the poison concerned did not act unaided or indiscriminately, and there were reasons for surmising that the sympathetic nervous was, in all likelihood, the intermediary in determining the localisation of the lesions. Evidence of this view was now brought forward. It was important to remember that sympathetic action was dependent upon the supply of adrenalin. The sympathetic nervous system, the adrenal bodies, and all chromaffin tissue must be considered as one in relation to the blood vascular system, and chromaffin tissues yield adrenalin or a similar chemical substance, and effects produced by this are almost all such as are produced by the sympathetic system. The sympathetic system is intimately linked up with the central nervous system; it has no true autonomy, and there are anatomical paths which provide for a constant interaction between both. Stimuli must be constantly passing from the sympathetic to the central nervous system, as there are special sense organs in the viscera and a definite sensory afferent path, and they certainly exercise physiological effects. Dr. Orr and Dr. Rows set out the plea of von Monakow for the material basis of the sentiments and emotions, and stated, in conclusion, that it was apparent that in nervous diseases, especially in those concerning the cerebrum, it was necessary to study, in the future, not only the more prominent symptoms dependent upon disturbed function of the central organ but also the collateral symptoms arising from disturbance of all the peripheral organs intimately connected with it. The problem could not be solved by a narrower programme.

Dr. BEDFORD PIERCE expressed the hope that the subject would be brought up again, with full opportunity for discussion, and spoke of a case of melancholia on which the paper seemed to throw much light.

Dr. ROWS replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Influenza.

A MEETING of this section was held on Nov. 15th, when Dr. G. PEACOCKE, the President, delivered his inaugural address on Influenza. It was, he thought, generally held that the causal organism was the *B. influenzæ*, though many held that some as yet undiscovered virus was responsible for the present epidemic. When uncomplicated, influenza did not often cause death, the high mortality of the present epidemic being almost entirely due to the presence of secondary infection with pneumococci and streptococci. The death-rate was not so formidable as was imagined—about 6·5 per cent. in his hospital practice and less than 2 per cent. in his private practice.

Symptoms.—Cyanosis was frequent with pulmonary complications, appearing early and persisting usually until death occurred. Laryngitis was extremely common. Delirium was often met with, and he had seen one case of mania. The temperature chart was often a fallacious guide, as severe cases often had only a moderate degree of pyrexia. An ominous sign was a fall of temperature without a corresponding fall in the pulse and respiratory rates. A moist and slightly furred tongue was a favourable sign, but if it were dry and thickly coated the chances of recovery were small. Vomiting was often distressing and alarming Slight albuminuria in the acute stage was common, but when severe the outlook was unfavourable. The pulmonary signs were varied—bronchitis or broncho-pneumonia was frequently present. A pulse-rate of 80, with a temperature of 102° to 103° F. was not uncommon, and during convalescence the pulse often became very slow, sometimes even 40 per minute. Jaundice was sometimes present, a tendency to hæmorrhages was common, especially epistaxis. Tonsillitis was rare. Otitis media should be recognised as of frequent occurrence. He had seen no case of influenzal meningitis. Dr. Peacocke noted particularly the outstanding form of the disease, in which death occurs with dramatic suddenness.

Treatment.—He usually employed salicylate of quinine. Aspirin appeared to relieve the headache. The bowels should be kept free and sleep should be promoted; he preferred calomel as a purgative and trional or some preparation of opium for sleeplessness. Stimulants were usually required and should be given freely.

Captain JOHN SPEARES gave an account of the disease, with special reference to the post-mortem findings and vaccine treatment. He concluded (1) that the mass of evidence showed that the present pandemic was caused by a bacillus which morphologically and structurally resembled Pfeiffer's; (2) that the fatal secondary pneumonia was caused mainly by a streptococcus hæmolyticus, which was frequently associated with hæmorrhagic tendencies; (3) that there was conclusive evidence of acute nephritis and albuminuria in severe cases; (4) that probably a certain degree of immunity was conferred by prophylactic use of influenza vaccine, and that the use of the vaccine for this purpose was justifiable; (5) further experiments, duly controlled, were necessary to establish the utility of influenza vaccine for prophylaxis and early treatment.

In the course of the discussion Dr. J. H. POLLOCK said that in his investigations at the Richmond Hospital on sputum, nasal discharge, empyema fluid, lung tissue, and heart's blood obtained post mortem, pneumococci or streptococci, or both, were always recoverable.

Professor E. J. MCWEENEY considered that the prevailing organisms were streptococci, pneumococci, and *Micrococcus catarrhalis*, these organisms being the cause of secondary pneumonias.

Dr. T. G. MOORHEAD noted the occurrence of severe meningeal symptoms, particularly in children, and asked if the influenza bacillus had been found in the cerebro-spinal fluid in any cases. He had found the fluid under tension, but sterile. He noted the frequency of post-influenzal delirium and mania, and post-influenzal empyema.

Dr. W. M. CROFTON thought that the microbes producing the complications—viz., staphylococci, strepto-pneumococci, and Gram-negative cocci—might be a primary infection along with the influenza bacillus, but that more frequently the patient's own catarrh microbes became pathogenic when his resistance was lowered by the influenza bacillus.

Dr. W. D. O'KELLY said that the fact that a vaccine containing no influenza bacilli seemed to protect against the disease as well as a pure influenza vaccine, suggested that a filter-passer was at fault, which might perhaps be present in the various vaccines used.

Dr. G. E. NESBITT said that in judging the results of protective inoculation it was necessary to remember the curious variations in susceptibility.

Dr. F. KENNEDY CAHILL thought that "suggestion" might act in cases of preventive inoculation, and quoted the case of a patient who developed all the symptoms of influenza except a temperature 16 hours after an injection of 1 c.cm. of sterile water. In the present epidemic the absence of post-influenzal profound prostration was remarkable.

Dr. W. BOXWELL regarded the severe types as cases of profound septic intoxication. He was not satisfied as to the results of vaccine treatment, but thought wholesale vaccination in the middle of an epidemic was dangerous, as was also the wholesale vaccination of contacts in a household. The time for vaccination was in the interval of recurring epidemics, but as the immunity was short-lived the value of prophylaxis in influenza was largely discounted.

SOCIÉTÉ DE BIOLOGIE, PARIS.

THE following is a summary of some of the papers read at the meeting of the society held on Dec. 7th:—

RUBINSTEIN and RADOVLIEVITCH. — Sero-diagnosis of Syphilis.

Le complexe inactivant l'alexine dans la réaction de Wassermann peut être isolé par l'action de l'eau distillée sur le mélange sérum + antigène. Ce complexe agit spécifiquement dans le cas des sérums chauffés et non spécifiquement dans le cas des sérums non chauffés. La spécificité a été décelée uniquement par sa capacité de fixer l'alexine.

CH. NICOLLE and CH. LEBAILLY.—The Spirochæte of Infectious Icterus.

Le virus d'origine murine de l'Institut Pasteur de Tunis a fait en un an 70 passages par cobayes. Un cheval de onze mois a reçu dans les veines 44 inoculations de ce virus; son sérum est préventif contre le virus humain français (L. Martin et A. Pettit). Les souris inoculées avec le virus de passage, conservent ce virus sans réagir pendant cent jours au moins, ainsi que le démontre l'inoculation de leurs organes aux cobayes de contrôle. Il y a là un moyen commode de transport et de conservation du virus.

W. MESTREZAT and ROMME.—Chemical Criterion for Secondary Suture.

Les auteurs ont déterminé sur une soixantaine de plaies, le rapport: $100 \times \frac{NH^3}{NaCl}$, le numérateur exprimant l'azote titrable au formol, exprimé en ammoniaque, le numérateur, le chlorure de sodium des compresses de pansements secs *en place depuis quarante-huit heures.* Les valeurs de ce quotient ont toujours été inférieures à 10 lorsque les sutures secondaires tentées ont été suivies de *succès complets.* Des incidents variables se sont produits supérieurs à 10. Les auteurs voient dans la détermination de l'indice formol d'une plaie un moyen précis de juger de l'opportunité d'une suture secondaire.

F ALBERT.—Route of Absorption of Tetanus Toxin.

L'absorption par voie sanguine prédomine. C'est par cette voie que la toxine gagne les centres nerveux. L'absorption par voie nerveuse pure ne donne jamais qu'un tétanos local. L'injection préventive confère à l'homme un certain pouvoir antitoxique. L'injection soit tardive soit insuffisante, confère une immunité relative. Cette immunité peut se dissiper (tétanos tardif).

Sir E. A. SHARPEY SCHAFER.—Functional Regeneration of the Vagus.

Les incitations nerveuses qui montent des alvéoles pulmonaires ne sont pas les seuls agents qui règlent le rythme normal de la respiration, car quand ces courants sont supprimés il s'établit bientôt un autre élément régulateur.

COMMISSION D'ALIMENTATION.—The Nitrogen Needs of the Body

En supposant le régime mixte le minimum exigible est de un gramme d'albuminoïdes par jour et par kilogramme de poids.

THE LATE MR. W. J. STEPHENS.—The death occurred at Brighton on Dec. 18th, in his sixty-fourth year, of Mr. William John Stephens, who at one time was one of the best-known medical practitioners in the borough. Compelled by ill-health a few years ago to retire from practice, he had during the war identified himself with various kinds of war work. A King's College man, he took the diploma of L.R.C.P.Edin. in 1882, and he spent practically all his medical life at Brighton. For 18 years he held the office of police surgeon, and at the time of his death he was in partnership with Dr. C. E. Maguire and Dr. W. A. Bowring.

Reviews and Notices of Books.

Fibroids and Allied Tumours. (Myoma and Adenomyoma.) By CUTHBERT LOCKYER, M.D., B.S., F.R.C.P., F.R.C.S. With 316 illustrations, including 37 coloured plates. London: Macmillan and Co. 1918. Pp. 603. 63*s.* net.

Dr. Lockyer holds an established position as an authority on the pathology of the pelvic organs in the female. He has had ample opportunities largely owing to the goodwill and coöperation of his colleagues over many years, and he has made good use of the abundant material put in his way, as this very valuable work proves. The book is, in our opinion, an example of what a monograph should be—complete, well written, containing not only the results of the author's large experience but also the best of what others have written on the subject. In one respect, however, it is lacking, and that is in the omission of complete references. A book of this description appeals only to the advanced student or to the teacher, and the omission in many instances of references is, to the latter at any rate, a serious defect.

The book is divided into three parts: the first part deals with Myomata of the Uterus, the second with those interesting and uncommon tumours, the Adenomyomata, and the third with the various operations practised for Myomata.

The pathology of the myomata is particularly well described and illustrated; indeed, one of the most striking features of the work is the lavish use of illustrations, both plain and coloured. Many of the latter are of great beauty. As might be expected, a good deal of space is devoted to a consideration of the various secondary changes in myomata, especially the commonest of all, hyaline degeneration. The author points out that red degeneration has attracted an amount of attention altogether out of proportion to its importance, and, as he says, the colour of the degenerating tumour is in most cases quite a side issue. Dr. Lockyer has no doubt about the occurrence of a myosarcoma, and the number of pathologists who would deny this at the present time must be very small. We cannot agree with the statement that the presence of myomata is a relative cause of sterility. Surely in most women the sterility precedes its development, and is rather the probable cause of the myoma. As the author a little further on points out, it is spinsters and sterile wives who suffer from myomata most commonly, and their sterility may well play a part in the etiology of these new growths. If we accept this view, then, the fact that interstitial tumours appear to delay conception is not difficult to explain. We notice a slight error on page 153. In the description of Dr. H. R. Spencer's case myomectomy "during delivery" should read "before delivery." It is interesting to note that the author's experience does not lead him to support at all strongly the view put forward by Bland-Sutton that the excessive uterine hæmorrhage in the case of fibroid tumours is associated with septic changes in the endometrium. In the most virulent cases of septic endometritis seen in cases of puerperal fever hæmorrhage is certainly not a symptom. The author, we are glad to see, is quite clear that there is no such thing as a myoma heart, apart from the changes due to the anæmia caused by the hæmorrhage.

The section on the diagnosis of the myomata is very helpful, and an interesting case is recorded of a cystic submucous myoma mistaken for pregnancy. In view of the prominence which has been given of late years to the use of X rays and radium in the treatment of myomata of the uterus, a considerable amount of space is devoted to these methods. On the whole the author is not very enthusiastic, but, as he admits, his personal experience is not large. The evolution of the operation of hysterectomy from a procedure with a mortality of 30 to 40 per cent. to one of 2 to 3 per cent. is one of the most interesting chapters in surgery, and the author does well to give a short résumé of the history of the operation. On the vexed question of the superiority of total hysterectomy to supravaginal amputation, Dr. Lockyer states that he now removes the whole uterus as a routine, but for spinsters and elderly married nulliparæ he thinks the supravaginal operation may well be retained.

Part II. deals with that curious and perplexing group of tumours, the adenomyomata, on which Dr. Lockyer has a great deal to say. Indeed, were it not that in this country these growths have not attracted the attention they deserve, we might regard the division of the subject as somewhat unequal when we find no less than nearly 180 pages devoted to this rare group of tumours. After a very interesting review of the main theories as to their origin, the author deals with their classification, and suggests that they may be considered under the two main groups of intra- and extra-uterine myomata. A great deal of information is given about the latter very interesting group, including adenomyomata of the round ligament, broad ligament, ovarian ligament, of the recto-genital space, and adenomyomata of the alimentary tract. This section is a most valuable one, forming the best critical review of this subject so far written in this country.

The third part of the book contains a full account of the various operations practised in the treatment of myomata. A useful section is included dealing with the after complications which may occur.

This book, in spite of its cost, will be indispensable to anyone engaged in the teaching of gynæcology; it will increase the author's already high reputation as a clinical pathologist, and it is a production on which we can most heartily congratulate him. The publishers are also to be congratulated for their part, as are the artists, for the beautiful illustrations which have been well reproduced.

The Life and Letters of Joseph Black, M.D. By Sir WILLIAM RAMSAY, K.C.B., F.R.S. Together with an Introduction dealing with the Life and Work of Sir William Ramsay, by F. G. DONNAN, F.R.S. London: Constable and Co. 1918. Pp. 148. 6*s.* 6*d.*

THE real artist and the genuine scientific worker may be said to belong to that class the members of which Lucretius designated as "divinitus invenientes"—i.e., as attaining what they sought by a kind of divine inspiration. This is obvious to most minds in the case of a musician, a painter, an architect, or sculptor. The works of Bach, Leonardo, Giotto, or of those nameless craftsmen who reared Rheims and the other great cathedrals in thirteenth-century France, stand out clearly to ear or eye. But the patient work of the chemist or the physicist is mostly hidden and in many instances stands in the same relation to its application as the acorn does to the oak. For no one who did not know could conceive on looking at an oak that it had sprung from an acorn, and likewise no one seeing the present-day applications of electrical power could imagine that they are all practically due to the fact that Faraday discovered that an electric current is induced in a conductor if it be moved across the poles of a magnet so as to cut the lines of magnetic force. Mendeléeff's Periodic Law and the gaps therein, together with the work of Lord Rayleigh and Ramsay on the inert gases, are further examples of the "divinitus invenientes." It is most appropriate therefore that Ramsay, the patient and accurate worker, should write an account of his great predecessor Black, to whose tireless, careful researches chemistry and physics owe such a debt. Moreover, Ramsay and Black were both educated at the same school of learning—namely, Glasgow College.

Sir William Ramsay has given us a charming biography of Black, illustrated with many extracts from his letters, with pictures of his contemporaries, and with at least one anecdote of an incident which occurred in the Senate Hall of Glasgow College during an official banquet.

"One of the guests was struck by the pale face of his neighbour, who appeared to be asleep—no extraordinary circumstance. 'What ails Drumsheugh?' he asked the man beside him, 'he's looking gey gash.' ''Sh man,' said he, 'he's been wi' his Maker thae twa hours.'"

Black's claim to immortality rests principally upon two researches, those dealing with "fixed air"—i.e., carbon dioxide—and those dealing with latent heat; in fact, he was the discoverer of both the gas and the condition. It is a curious instance of the irony of history that the incentive of Black's research was the desire to discover a mild alkali for the cure of calculus in the bladder, and that this desire was fostered by the Government having given a quack £1000 for the prescription of a medicine for the same.

We have no need to describe Black's patient and masterly investigation, together with his "proof that the change of a complex compound to simpler compounds, and the building up of a complex compound from simpler ones, can be followed successfully by the use of the balance"; but everyone who is interested in the progress of human thought should read Sir William Ramsay's charming account thereof.

Black died in 1799 in his seventy-first year; his passing was in accordance with his whole life, perfectly quiet and unembarrassed:—

"Being at table with his usual fare, some bread, a few prunes, and a measured quantity of milk diluted with water, and having the cup in his hand when the last stroke of his pulse was to be given, he set it down on his knees which were joined together, he kept it steady with his hand, in the manner of a person perfectly at ease; and in this attitude expired without spilling a drop, and without a writhe in his countenance; as if an experiment had been required to show to his friends the facility with which he departed."

Married Love: A New Contribution to the Solution of Sex Difficulties. A Book for Married Couples. By Dr. MARIE STOPES. With a Preface by Dr. JESSIE MURRAY and Some Striking Letters. London: A. C. Fifield. 1918. 5*s*.

THIS is an extremely sensible little book; it deals in the most intimate way with normal sexual life, and by sheer frankness remains decent. Of the things which are commonly accepted as sound physiology we need only say that they are also things which thousands of people would be the happier for knowing, though they cannot be made part of any public syllabus of secondary education. Nor can parents, guardians, or older friends be commonly regarded as the proper sources of such information—some will not possess it, still more would resent the mentor's task, and more again, we believe, would be quite unable to impart it. This is to say that the book is really needed as a public adviser.

The fourth chapter and the fifth, the two which deal absolutely with the sexual act, contain the essential message of the author, which may be summed up by adopting her own words, that the act is, or should be, a triple consummation, symbolising spiritual union, giving intense pleasure, and originating new life by fusion. The fourth chapter, entitled "The Fundamental Pulse," gives the evidence upon which the author has erected simple curves indicating the normal dates of the upwelling of natural desire in women in relation to the dates of menstruation, and it is with these postulates in mind that the fifth chapter, "Mutual Adjustment," must be read. That such rhythm is present in the usual woman's sexual life is well known to medical men, and we believe that the author's curves represent the physiological facts, though, as Dr. Jessie Murray says in her prefatory note, further observation is required to support the detailed theories.

LIBRARY TABLE.

Medical Annual for 1918. Bristol: John Wright and Sons, Ltd. Pp. 716. 10*s*. net.—Notwithstanding the difficulties with which its production is beset owing to the exigencies of military service, the *Medical Annual* of 1918 fully reaches the high standard set by the editor and publisher in previous years. The treatment of war conditions occupies a fair proportion of the volume, Deputy Surgeon-General A. G. Wildey, R.N., being responsible for an account of the treatment of wounds, the results of which still remain. Of special interest is Mr. W. I. de Courcy Wheeler's account of the work of the orthopædic centres under the general supervision of Sir Robert Jones. Mr. W. H. Dolamore contributes a well-illustrated description of the treatment of gunshot injuries of the jaws and face, showing the triumph of plastic surgery over unsightly deformity and functional disability. Malingering is dealt with by Mr. A. Bassett Jones and Mr. R. Ll. J. Llewellyn. The contribution of Dr. Carey F. Coombs on diseases of the heart is directed against the very prevalent mistake of attaching too great importance to auscultatory phenomena. In his experience numbers of men have been rejected from enlistment or recommended for invaliding out of the Army on no surer ground than the presence of an unimportant and often transitory murmur. Two new features add to the utility of the volume as a book of reference—the addition of a list of contributions to the name of each contributor, and an introduction by the editor consisting of a review of the year's work. This Annual should be in the hands of every member of the profession who wishes to keep abreast of medical knowledge.

Musings of a Medico. By KENNETH ROGERS, M.D. Lond. London: Erskine Macdonald, Ltd. Pp. 70. 3*s*. 6*d*. net.—Dr. Kenneth Rogers's little book of verse is divided into three parts; general verses, verses suggested by the war, and sonnets, closing with half a dozen pieces of irregular shape. He has put his more ambitious work into the sonnets, but of course it is exactly in the sonnets that the craftsman must expect to receive the severest inspection, and we feel that Dr. Rogers succeeds best in humbler flights. "The Lament of an Old Buffer" or, "On Man, Bees, and Flowers," latter being suggested in part by M. Maeterlinck's "L'Intelligence des Fleurs," and the rhyme of "The Dragon Fly" are all metrical exercises to which considerable feeling has gone. The little book is notable for the author's love of flowers.

Casting out Fear. By FLORA BIGELOW GUEST. Second edition. London: John Lane. 1918. Pp. 94. 3*s*. 6*d*.—Beginning with the paralysing effect of fear in general on all useful human activities, the author devotes 22 short chapters to particular fears, from the fear of heredity to the fear of death. Her epilogue runs:

> Let us cast out all Fear.
> Let the sun in at our windows.
> Let the sun into our souls.

And, whether consciously or not, she has adopted the method of the psycho-analyst to achieve this desirable result. She analyses in simple and striking language the genesis of phobias, and without making any claim to specialist knowledge contrives to say many helpful things—Chapter IV., on Educating Children in Fear, is very apposite. At a time when fear is being increasingly recognised as a motive in human conduct, we commend Mrs. Guest's little book to thoughtful study.

Home Nursing. Arranged According to the Revised Syllabus of the St. John Ambulance Association. London: St. John's Gate, Clerkenwell. Pp. 272. 1*s*. 6*d*.—This little book has been compiled by a committee from a manuscript written at the request of the St. John Ambulance Association by Miss Heather-Bigg, R.R.C., matron of Charing Cross Hospital. The arrangement of the manual is similar to that of the First Aid Manual, each chapter being followed by questions, with the pages indicated on which the answers may be found; an excellent method for enabling the student to revise and check knowledge. Beginning with a summary of the qualifications of a nurse, just so much physiology as is needful is given, followed by a succinct account of the duties of a home nurse, technical terms being sparingly used, while those absolutely necessary are included in a glossary. The avowed objects of the manual are: (1) to serve as a guide to a course of study directed by a medical man or trained nurse; and (2) to form a book of reference for those who have obtained home nursing certificates and are called upon to undertake the care of a patient where trained nursing is unobtainable, or where the illness is so slight that a professional nurse is unnecessary. These objects are well met in "Home Nursing."

JOURNALS.

The American Review of Tuberculosis. Baltimore: National Association for the Study and Prevention of Tuberculosis. 35 cents.—The September number contains several interesting papers on the war-time problems of tuberculosis in the United States of America, in Canada, and in France. Dr. George E. Bushnell reviews the results of the National Tuberculosis Association's programme, adopted by the Surgeon-General, for re-examining the American Army for tuberculosis. Nearly 450 physicians were engaged on this task, and about 10,000 men were found to be tuberculous within a month or two of enlisting. By eliminating these men, who would otherwise have become chargeable to the State, these examinations may be said to have saved $50,000,000 of public money. This calculation suggests that the interests of the State and the individual are diametrically opposed. A saner and more generous view is reflected in the Surgeon-General's statement, published in the Official Bulletin, to the effect that the soldier, disabled on duty, shall not be discharged before as complete recovery as possible has been effected. Dr. Bushnell draws attention to the great difficulty of distinguishing pulmonary tuberculosis from the present serious epidemic of hæmolytic streptococcal bronchitis and broncho-pneumonia. The clinical picture is, he says, exceedingly similar to that of pulmonary tuberculosis. Hence the order that no soldier shall be discharged for pulmonary tuberculosis unless tubercle bacilli have been found in the sputum. According to Dr. Bushnell, there is a movement on foot in the United States for standardisation of treatment, special courses of instruction being provided for medical men. These courses, it is hoped, will largely prevent contradictory instructions being given to the patient as he passes from one hospital to another. Dr. Bushnell does not say how such a notorious bone of contention as tuberculin treatment is to be fitted into the scheme of standardised therapy.

THE LANCET.

LONDON: SATURDAY, DECEMBER 28, 1918.

State Organised Pharmacological Research.

OUR attention has been drawn to a movement begun by the Government of Bombay in the direction of establishing a pharmacological laboratory and research institute for the investigation of drugs, and more particularly the indigenous drugs of India. A committee has been formed, with Lieutenant-Colonel A. STREET, M.B., F.R.C.S., I.M.S., as its chairman. The committee is to inquire what pharmacological research is being done in other parts of India, so that developments in Bombay may be coördinated, so far as is possible, with similar efforts elsewhere; and the committee is further asked to obtain information as to what is being done in the direction of pharmacological research in this country. The inquiry is opportune in a big drug-producing country like India, but, more than that, it raises the suggestion which might well receive serious consideration at home—the desirability of organising and establishing a State controlled laboratory for pharmacological research in the motherland.

We are under the impression that so far this important branch of scientific work has mainly been undertaken by private enterprise and by our great leading houses of pharmacy and chemical manufacture—at considerable cost. Certain University laboratories have, it is true, also undertaken analytical work, but not on any large scale. Very valuable work has thus been done, as the columns of the Chemical Society's Journal and those of the *Pharmaceutical Journal* show, and we have recorded the more important departures as they occurred, but clearly the scope of such work would be considerably widened if a reference could be made to a State pharmacological department. The Pharmaceutical Society, we know, maintains a school of pharmacy, which is under the direction of Professor H. L. SMITH, who occupies the chair of chemistry, and Professor H. G. GREENISH, who is responsible for the department of pharmaceutics; and valuable communications from the pharmacy research laboratory of the society appear from time to time in the columns of its official journal. We may refer to one article which appears in the last number of the *Pharmaceutical Journal* as a specimen of pharmacological research from this laboratory. It comes as a sequel to a note in our own columns on the use by the natives in the Central Transvaal of croton bark as a remedy for bilious malarial fever.[1] We know also of the existence of a scientific and technical department of the Imperial Institute, which has doubtless carried out investigations of national importance. This work, however, relates chiefly to the raw materials produced in our colonies in regard to their composition and utilisation, and the object is rather to give advice respecting industrial development and tropical agriculture. When the examination of raw drug materials is undertaken by this department, it would appear from the published reports that the references have been chiefly to the commercial development of certain colonial products, to the encouragement of their cultivation, and to other matters which do not call for pharmacological investigation.

In all schemes of research organised and controlled by the State the well-equipped pharmacological laboratory should take a place, and here special facilities should be afforded for bringing to light the medicinal value of raw materials. It is for a State department of this kind to take up a branch of research calculated to advance in general the pharmacology of drugs. So far as we are aware, no such department exists or ever has existed, and our knowledge of the essentials of plants, roots, barks, and so forth, used in medicine, has been due to independent research undertaken by the private individual. The separation and recognition of definite principles—for example, those in opium, nux vomica, cinchona, ipecacuanha—occur as a valuable record of the voluntary work of the medical man, the analyst and pharmacist acting in a private capacity. Such a position of things has narrowed the scope of pharmacological investigation in the past, and what is wanted in the future is a court of reference which can be trusted to take up the important issues arising when new remedies are announced. Moreover, such an institution should help in the work of establishing a relation between physiological action and chemical constitution and remove much empiricism from medical treatment.

[1] THE LANCET, Sept. 30th, 1899, p. 873.

King Edward's Hospital Fund for London.

AT a meeting of the Governors and General Council of the King Edward's Hospital Fund for London, called for the purpose of awarding the grants for the present year to hospitals, convalescent homes, and sanatoriums, Lord REVELSTOKE, in his capacity as treasurer, had the pleasurable duty of stating that the total receipts for 1918, up to, and including, the first week in December, amounted to £174,531, all expenses having been deducted, and the contribution from the League of Mercy not being added. Sir WILLIAM COLLINS, in making the annual statement on behalf of the League, reminded the meeting that during its 20 years of existence it had contributed to the voluntary hospitals in and around London £305,280. The figures given by Lord REVELSTOKE showed that the Fund had with its bankers, or at short call, sufficient money to meet the whole of the sum which it had been decided to distribute for the year 1918, amounting in all to £200,000. This is a notable achievement.

The report of the Distribution Committee, presented by Sir WILLIAM CHURCH, stated that the sum of £190,000 was to be distributed among London Hospitals, 103 in number, the remaining £10,000

being allocated to various Consumption Sanatoriums —£7825, and Convalescent Homes—£2175. The £190,000 destined for hospitals is £9000 in excess of the sum distributed in 1917, £27,500 in excess of that distributed in 1916, and £40,500 in excess of that distributed in 1913, the year before the war, although the buying power of the total has doubtless diminished during the same time. Of the total distributed over £160,000 is being applied in the form of grants to maintenance, leaving £29,750 as capital grants. Of these capital grants £10,100 is being employed in reduction of capital liabilities incurred before the war, £15,500 has been ear-marked for schemes of improvement, and the remainder represents the sums sanctioned for schemes of extreme urgency during the war. While the war was proceeding the Distribution Committee discouraged the issue of public appeals in aid of schemes which were not of extreme urgency, but in 1917 some capital grants were sanctioned in aid of deferred schemes, and early this year the Committee was announced to be ready to consider proposals for the immediate issue of appeals for post-war schemes on certain conditions—the main one of which was that in such appeals it should be clearly stated that the contributions received in response might be used either for building or for endowment. In this way hospitals would not be committed in advance to extensions which might later be found inadvisable. As a matter of fact, if all the schemes of extension which have come before the Fund were to materialise the available accommodation of the voluntary hospitals of London would be increased by no less than 1750 beds. It is quite clear that if any increase of this sort is contemplated the whole question should be considered from the point of view of the total needs of the metropolitan population and the geographical position of the institutions. The value of the work of the Fund is especially shown in its readiness to look at the voluntary hospitals of London as one public service and not as a congeries of rival charities.

The report of the Distribution Committee announces also the receipt of proposals for the amalgamation of University College Hospital and the Royal Ear Hospital, whereby the latter, which has been closed during the war, will be reopened as a special department of the large general institution. The Distribution Committee is supporting the working out of this scheme by grants. This amalgamation, following on that of the Hospital for Diseases of the Throat, Golden-square, with the London Throat Hospital reduces the number of ear, nose, and throat hospitals applying for a grant from five to three, of which only two are now on the books of the Fund. This is another indication of the way in which the Fund desires to bring order into hospital service for the vast London population by preventing overlapping of energies; but of course the process of fusing hospitals, general or special, with each other introduces the question of selecting the honorary staffs. We trust that those responsible for the management of King Edward's Fund will bear in mind the real difficulty that often underlies the position.

Annotations.

"Ne quid nimis."

LETHARGIC ENCEPHALITIS AND POLIOMYELITIS

THE difficulty of calling by an intelligible name such diseases as lethargic encephalitis and anterior poliomyelitis when the morbid agent is unknown and the morbid lesions are so various must not obscure the fact that a stage of useful knowledge has been reached in regard to the two diseases and their relations. In his lecture on lethargic encephalitis delivered before the Medical Society of London, which appeared in our issue of Dec. 21st, Dr. Farquhar Buzzard drew some general conclusions with regard to the recent epidemic. He directed attention to the fact that in the case of the analogous disease, acute poliomyelitis, the profession as a whole has tended to take too limited a view. In this it has followed the course of the history of the disease, in which our knowledge was for a long time based upon late examination of sporadic cases. It was not until epidemics occurred that attention was directed sufficiently to the protean character of the disease, due to the very variable localisation of the morbid process. Because the most common site was in the spinal cord and the most vulnerable elements the cells of the anterior horns the disease received the name "anterior poliomyelitis," and this stereotyped our conception of it. Dr. Buzzard has rendered a service by warning against a similar limitation of view in the case of lethargic encephalitis. This disease presents many points of similarity to acute poliomyelitis, but is "undoubtedly an entirely different disease." The form in which it was first observed was characterised by lethargy, asthenia, and oculo-motor paralysis; a second group of cases present the features of acute paralysis agitans. Dr. Buzzard describes a third group in which "the force of the inflammation was spent upon the cerebral cortex," with resultant Jacksonian movements and consecutive paralysis. In different cases the distribution of the lesions may be very various, and no doubt other types of case will be described later. The number of cases recorded in the present epidemic has been comparatively small, and they have occurred over a wide area, as shown in the note on the distribution of the disease by Lieutenant-Colonel S. P. James in the same issue of THE LANCET. It is probable that many other cases have occurred which have not been recognised as such, because they did not conform in type with the variety of the disease which was first described, and that later an "abortive" form of lethargic encephalitis may be established, as has been done by Wickmann in the case of poliomyelitis. Dr. Buzzard suggests that some sporadic cases of encephalitis lethargica have previously been diagnosed as cerebral thrombosis or hæmorrhage; he points out that microscopical examination is frequently the only method of differentiating between the two, the naked eye appearances being indistinguishable. This would explain those cases of "cerebral thrombosis" in which the Wassermann reaction is negative and the vascular system apparently healthy. Unfortunately, our ignorance of the causal agent is so complete that but little help in treatment is afforded by such a differentiation, beyond confirming our belief that the cause is one associated with a profound toxæmia against which general measures can be taken.

TROPICAL DISEASES IN THE BALKANIC WAR ZONE.

IN his paper read before the Royal Microscopical Society on Dec. 18th, Dr. Aldo Castellani, Lieutenant-Colonel, Italian A.M.C., described the tropical diseases commonly met with in the Balkanic zone during the war. Of these, he said, the most important and the commonest was malaria, which had often taken on a malignant character and had given endless trouble by simulating many other diseases. Only a routine blood examination can exclude errors in diagnosis. Next to malaria the dysenteries, amœbic and bacillary, were the commonest affections. Enteritis due to flagellates had occurred, and more rarely a form with a ciliate infection. Coccidiosis was also observed. Cholera and paracholera had been rare, although a choleraic type of bacterial dysentery had been observed. and a form of diarrhœa was seen in starving Serbian soldiers during the Albanian retreat which closely resembled the famine diarrhœa of India. Camp jaundice (*Icterus castrensis*) had been common. Dr. Castellani distinguishes two varieties: (1) a very severe type (*gravis*), hæmorrhagic, with high fever lasting 10 to 12 days, and occasionally relapsing —this is true Weil's disease, and fortunately rare; (2) the common mild type (*levis*), often afebrile, but probably in many cases spirochætic in origin, like the severe form. Fevers of the enteric group, fairly frequent in the Balkans, had not during the last year assumed epidemic type. Paratyphoid A and B were in certain districts more frequently met with than true typhoid. Fevers resembling paratyphoid but due to intermediate germs had also been noted. Colonel Castellani and G. A. Lurie found in some cases the *Bacillus colombensis* as causal agent. Not infrequently mixed infections were found in all the three possible combinations—viz., T.A., T.B., and A.B.; while two cases of triple infection, T.A.B., had been confirmed by hæmocultures. The method of combined vaccination devised by Dr. Castellani had given, he thought, good results, and the Serbian Army officially adopted a tetravaccine, T.A.B. + cholera. Malta fever, rare in Macedonia itself and the interior of the zone, was more frequently met with on the coast and in the adjacent islands. Kala-azar did not occur in Balkan adults, but many cases of the infantile type were seen in certain islands of the Adriatic and Ægean seas. Relapsing fever was common, and in its treatment the best results had been obtained by the combined use of salvarsan and tartar emetic. At the moment, he said, typhus exanthematicus was very rare, in striking contrast to the terrible epidemic which raged in 1914–15. Trench fever was occasionally met with in both the types described in France. Pappataci fever was extremely common in certain parts of the Balkans, especially in the late summer and early autumn. Broncho-mycosis and broncho-spirochætosis were far from rare. Pellagra was also quite common in several districts in Macedonia. Of the tropical diseases of rarer occurrence Dr. Castellani instanced blackwater fever, filariasis, leprosy, sprue, intestinal myiasis, mycotic, spirochætic, and flagellate urethritis. Certain tropical skin diseases of frequent occurrence gave rise to much discomfort in summer, and were often wrongly diagnosed. Such were dermatitis interdigitalis epidermophytica, or "mango toe"; tinea cruris, or "dhobie itch"; prickly heat; and various types of tropical pyosis, such as Mansoni and discoides. In 1915 Dr. Castellani saw among Macedonian peasants cases of ulcus tropicum, Oriental sore, ulcus infantum, blastomycosis, sporotrichosis, and acladiosis, and also numerous cases of trichomycosis axillaris flava, nigra, et rubra, of intertrigo saccharomycetica, and various other hyphomycetic affections. He had also reported two cases of Madura foot, two of keratoma plantare sulcatum, and one (typical) of ainhum. Dr. Castellani concluded with a strong plea for the routine microscopical examinations in all patients. The wealth of diagnostic problems among the conditions which he has described makes such a plea eminently reasonable.

AUTOTHERAPY IN INFLUENZA.

Dr. Luigi Meille draws attention in a recent issue of *Il Policlinico* (Practical Section, Nov. 3rd, 1918) to a method of introducing into the organism of a patient suffering from a severe form of influenza a non-heterogeneous serum which presumably contains the antibodies or antitoxins of the antigen or toxin which produces the disease, and which, beyond its own antitoxic properties, would also act as a producer of fresh antitoxins. The technique is extremely simple. The veins at the bend of the elbow having been made prominent by the application of an elastic ligature, the needle of a sterilised syringe of 10 c.cm. capacity with the piston down is introduced into one of them and the blood allowed to push back the piston and flow into the syringe. An amount of 20 or 30 c.cm. thus obtained by repeatedly detaching the syringe from the needle is emptied into a sterilised test-tube, which is then plugged with cotton-wool and covered with guttapercha. By keeping the test-tube in a slanting position for 12 hours the serum separates and 1 to 2 c.cm. are aspirated by a syringe and injected into the subcutaneous tissue of the patient. No local reaction follows, but after from three to four hours a slight febrile reaction may occur, which soon subsides without leaving any after-effects; serum disease is never observed. Dr. Meille states that the action of the serum is quickly shown by an improvement in the course of the disease; the pulse becomes stronger, cyanosis less marked, and delirium ceases. Autoserotherapy has no specific action upon complications, except by improving the general condition of the patient and favourably influencing the course of the disease.

BENJAMIN RUSH.

THE services of Benjamin Rush to American education have been well brought out by Dr. Harry G. Good, Ph.D., of Bluffton College, Berne, Indiana. At last justice has been done to the non-medical side of his life. Not without reason did Rush's friend, J. C. Lettsom, call him the American Sydenham; but he was more than physician—he was author, philanthropist, patriot, and statesman. And above all he was a brave, strong man. As Bancroft, the historian, says: "When an infectious pestilence raging in Philadelphia rapidly swept nearly 4000 to the grave Rush despised every consideration of personal safety, and was so true, night and day, to his patients that it was said of him in Europe: 'Not Philadelphia alone, but mankind, should raise him a statue.'" He was perhaps the greatest pupil of William Cullen, whose system he championed in opposition to that of Boerhaave. Chapter III. of Professor Good's work deals with the professional side of Rush's life. Apart from his psychological studies, his contributions to practical medicine have been excelled by many of his countrymen, but it would be hard to name any other who occupies the same distinguished position as a

far-seeing reformer in social and educational affairs. A fearless abolitionist, at a time (and place) when only a strong man could hold such opinions—a humanitarian in his life-long advocacy of penal reform—an ardent temperance advocate whose writings on the subject are still current—an enlightened student of insanity and an early supporter of the humane treatment of its victims—a friend of animals and an incessant pleader for their kindly treatment—such was Benjamin Rush. And beyond all this it is as an educational reformer, rather than as a physician or a patriot, that he is best remembered to-day. It is just here that Sir William Osler finds the special value of Professor Good's book. "It contains," he says, "a critical study of Rush's activities in the establishment of public schools, in the promotion of the higher education of women, in the necessity of national universities, and in the importance of bringing scientific knowledge into the daily life of the home, the farm, the workshop, and commerce. Professor Good constantly reminds one of Locke in his good sense about the education of children; and what a happy criticism to say that punishments meted out indiscriminately to boys for ignorance and immorality confuse their moral sense! For the first time we have here set forth clearly the lifelong work of Rush as an educational reformer, and to Dr. Good as a professor of the subject this has been a labour of love. The profession on both sides of the Atlantic is indebted to him for this interesting picture of one of the most versatile and distinguished of its members. I may add that we have as an appendix a full and accurate bibliography."

MYALGIA OR TRENCH FEVER.

MYALGIA is the name given to a painful affection, apparently involving the muscles or fasciæ. The connexion with true rheumatism is not always obvious, nor is it even certain that the muscles or fasciæ are really involved; but the disorder is often the direct result of damp or cold, or of excessive muscular exertion or strain. Possibly toxins or poisons absorbed from the alimentary canal are responsible for some muscular pains. Thus far Sir Frederick Taylor, and we need hardly look further for a demonstration of the weak nature of the evidence connecting myalgia with rheumatism. A generation ago muscular rheumatism was presumed to be associated with a gouty tendency and lithæmia. The crisp Anglo-American view we should expect to find in Osler and McCrae's System is not there; myalgia is simply ignored. Dieulafoy also has nothing to say on the matter. It remained for the trenches to throw light on this as on other common ailments; for "trench shin" and disabling muscular pains clamoured for investigation. The identification of trench shin as one type of trench fever[1] was made early and is now generally accepted. In a letter to our correspondence columns this week, commenting upon Dr. R. D. Rudolf's "Trench Fever Cachexia,"[2] Mr. A. Bertram Soltau, Colonel, A.M.S., gives reasons for thinking that nearly 80 per cent. of the myalgias of active service are due to the toxins of trench fever. In March last Mr. Soltau circulated a note to all Army medical officers in Flanders calling attention to the great variety of pains associated with trench fever, most of them, however, originating in the fibrous insertion of muscles. The nocturnal exacerbation of the pain and the fact that it is generally increased by warmth negative a muscular origin and distinguish the condition from a true myalgia. Trench fever pain has therewith reached some measure of precise description. It is not unlikely that a comparative study of ordinary so-called muscular rheumatism may establish the same or a similar toxic origin.

ALCOHOL FOR INFLUENZA PATIENTS.

IN view of representations that have been made that there is in some districts a shortage of spirits required in treatment of patients suffering from influenza, arrangements are being made by the Ministry of Food that in the event of information reaching the Ministry indicating that an additional supply of spirits is necessary in any particular district for the treatment of such patients the Ministry will direct a special supply to that district. Steps are being taken by the Ministry to obtain representative medical opinion as to the reality and extent of the need in the various localities affected. All bottles of spirits supplied for this purpose will bear distinctive labels and will only be sold against a certificate from the doctor attending the patient.

THE PREVENTION OF SYPHILIS AMONG INFANTS.

THE generous gift of £10,000 by the Grocers' Company made it possible for the London Hospital to build wards for the treatment of venereal diseases. In-patient treatment is obviously of special urgency in the case of pregnant women infected with syphilis, and this section of the work is beginning to show results in the form of healthy offspring. It was a happy thought on the part of Dr. J. H. Sequeira to combine an "At home," given, on Dec. 18th, to some of the mothers and children who have benefited from treatment, with a medical gathering where the lessons already learned and their further application in the future would be discussed. Lord Knutsford drew attention to the large number of East-End women who miscarried as the result of syphilis, in whom proper treatment would have ensured the birth of children showing no traces of disease. There was need, he said, for other districts and hospitals to organise on a large scale to provide similar treatment. The venereal diseases department of the hospital was supplied with patients by its own obstetric and maternity departments, through the maternity almoners, from the City of London Lying-in Hospital, and by various maternity centres in the neighbourhood. Dr. Sequeira added that both married and unmarried women were dealt with, and since March, 1916, 52 pregnant women had been treated. After treatment in the special department these women were either admitted to the general lying-in ward or were attended by the out-patient charities under the supervision of the obstetric physician to the hospital. He added that, in his opinion, the women after treatment were not liable to infect others, either in the ward or outside, if the usual precautions were taken. In the East-End coöperation between the maternity and infant-welfare centres and the venereal clinic at the hospital was actually very good. He had found it safe in practice to give injections of salvarsan to pregnant women, and thought it essential to treat every such patient at

the earliest possible moment. Sir Arthur Newsholme also emphasised the need for coöperation between venereal clinics, child-welfare and maternity centres and the general practitioner. But coöperation, however necessary, will prove futile without the provision of hospital accommodation. The need of further facilities for the treatment of syphilitic pregnant women as in-patients is very great, and sufficient hospital accommodation must be provided for them both before and during confinement. In London the Thavies Inn Venereal Centre for Pregnant Women provides the only other residential treatment, and the encouraging results obtained there were described in THE LANCET of Dec. 7th by Mr. John Adams. Coöperation and increased accommodation are the two essentials in the solution of a problem which brooks no delay.

THE SCOTTISH UNIVERSITIES ELECTION.

WE have received a letter from Mr. R. W. Cockburn, agent for Professor W. R. Smith in this election, in which the statement is apparently maintained that Professor Smith was "adopted by the Medical (Parliamentary) Committee for this constituency." He was not so adopted. Upon Professor Smith, at a meeting of the Committee, mentioning that he might not be elected for the Scottish Universities, his name was added to a general list of medical candidates whose wishes to find a constituency the Committee was willing to further. The Committee's policy is to assist medical men to get into Parliament, and with that object in view an offer was made to Professor Smith, and to all other medical candidates for Parliament, to try to find speakers, political views and individual candidature having nothing to do with that offer. In a circular letter to the Editor of THE LANCET, headed "The Scottish Universities Parliamentary Association," Sir Thomas Oliver, as chairman of the Association, says, "Professor Smith has also been adopted by the Parliamentary Committee." The one and only inference must be that Professor Smith was adopted as a candidate in relation to the Scottish Universities vacancy, and that inference, if drawn, would have been incorrect.

Sir William Whitla has been returned by a very large majority as Member for Queen's University, Belfast. Sir Robert Woods, standing as an Independent, has been returned for one of the Dublin University seats.

Dr. Sydney Russell Wells has been appointed to represent the University of London on the General Council of Medical Education and Registration.

M. Albert Calmette, director of the Pasteur Institute at Lille, has succeeded M. Emile Roux as director of the parent institute in Paris.

Sir Robert Philip has been elected President of the Royal College of Physicians of Edinburgh, and Dr. A. H. Freeland Barbour, Vice-President.

THE appointments to the Industrial Fatigue Research Board have now been completed and include, in addition to the names given in THE LANCET of Nov. 23rd (p. 718), those of Mr. Kenneth Lee, Mr. R. R. Bannatyne (representing the Home Office), and Dr. C. S. Myers, F.R.S., Director of the Psychological Laboratory, Cambridge. The Board expresses its readiness to consider any suggestions submitted to the secretary at 15, Great George-street, London, S.W. 1.

THE ANNUAL REPORT FOR 1917 OF THE CHIEF MEDICAL OFFICER OF THE BOARD OF EDUCATION.

II.[1]

EVERY chapter of Sir George Newman's report brings into relief some fresh aspect of the physical condition of the children which must be of absorbing interest to all who have at heart the moral and material welfare of the people. The keynote of the whole report is insistence upon the importance of the *positive* function of school hygiene, the education and building up, the strengthening and development of the natural powers of the body of the normal child, that it may be able not only to resist disease, but to become its best. It is clear that there has hitherto existed on the part of the local education authorities a misunderstanding of the true principles involved, a failure to attain to the necessary breadth of vision. They have thought their duty done with the carrying out of what Sir George Newman terms the *negative* function of school hygiene, the arrangements for treatment of the defective child. It is the ordinary child who is the key to the nation's health, and it is the adaptation of the environment, so that Nature may have its way and the child grow in body and mind, that the local education authority must make its business. Hence the need for physical exercises, games, school meals, play-centres, and open-air lessons; for vigilance and strict control of premature employment; for the claims for more sleep at night and more rest in the day.

School Dental Work.

Not that even the negative function has been hitherto well and conscientiously performed; far from it. Despite the facts that are known with regard to the condition of the children's teeth and the resultant loss of physical efficiency in the population, and despite the fact that local education authorities for ten years have had the legal power, we learn from the report that a beginning, at present incomplete and inadequate, has been made in 151 areas, but in 167 educational areas the authority has undertaken no dental treatment at all.

The Board have suggested that an authority's school dental scheme should at least provide for—

(i.) The inspection and treatment of children of 6–8 years of age.

(ii.) The re-examination at intervals of not more than one year of children who have already received treatment and the provision of supplementary treatment where required.

(iii.) The periodical inspection and treatment of other children as may be necessary and of "specials."

At present no large authority is carrying out this complete scheme, and few are doing more than examine and treat the 6–8 age-group. The extent to which school children at these ages require dental treatment is shown by the findings of school dentists in different areas, and these for 1917 vary from 79 and 80 per cent. in London and Liverpool respectively to 97 and 99 per cent. in Southport and Wrexham.

The Board have advised that dental inspection should be carried out only by qualified dentists, and preferably those undertaking subsequent treatment; but in exceptional cases, particularly rural areas, they are prepared to accept proposals for the carrying out of dental inspection by the school doctor, provided only that he is exceptionally qualified. With regard to dental treatment, the services at present rendered "probably do not cover more than about one-tenth of what is required to deal with half the school population." The three great difficulties in the way are stated to be: first, the grave shortage of dentists; secondly, the unattractiveness of school dental work; and, thirdly, the unwillingness of authorities to incur the expenditure of a scheme. About this third difficulty there is no doubt, and our experience is that the first two difficulties are merely cloaks brought forward to hide the third. However this may be, the alleged difficulties have led a few authorities to make the proposal to the Board that they should use unqualified "dental dressers" who, with the help of school nurses, would, it is suggested, be able to deal with a large portion of the school dental work. It appears that schemes on these lines are actually in being. Now these proposals cut at the root of much that is of fundamental importance in medical practice,

[1] No. I. was published in THE LANCET of Dec. 21st, 1918, p. 855.

and it behoves the profession to scrutinise them with meticulous care. It is stated that the British Dental Association considered this question of "dental dressers" and reported in guarded terms in July, 1917, and the subject is, moreover, under the consideration of the Dentists Act Committee of the Privy Council.

We have no wish to allow any punctilios of professional etiquette or of medical tradition to stand in the way of any reform or of any arrangements which may be necessary for improving the condition of the nation's children. And professional pride must be denied and set aside and mortified if it obstructs any proposal proved on economic grounds to be absolutely necessary. But we must say that on present showing the motive of the present proposal appears not to be necessity but parsimony. At any rate, it appears to us perfectly extraordinary that Sir George Newman should solemnly set down as one of the things that could be done by unqualified dental dressers that very inspection of the teeth of the children which he has already defined as a work requiring such skill that it cannot in general be entrusted under the Board's rules to the school medical officer himself or to the experienced school doctors working under him. We trust it may be long ere our professional pride be again so mortified, and we may be forgiven if we feel naughtily thankful for the existence of a Dentists Act Committee and if we desire more power to its elbow, especially as we gather that, owing to the reference of these questions to that Committee, "further action has been suspended" for the moment.

Special Schools and Open-Air Schools.

"A substantial part of the medical treatment of a certain group of defective children—blind, deaf, feeble-minded, epileptic, and tuberculous—is a special form and character of education." We therefore have "special schools" for about 1 per cent. of the total school population. During the year 1917 there was an increase of 8 schools for the blind, 6 for the tuberculous, 4 open-air schools, and 3 others, making a total of 21 schools. The number of scholars on the registers of special schools in January, 1918, was 30,695, including 2520 blind, 3938 deaf, 14,343 mentally defective, and 5792 physically defective. It has been estimated that the number of physically defective children in England and Wales is between 35,000 and 40,000, but up to the present only 25 local education authorities have provided day schools and 7 have provided residential schools. It is the possibility of making such statements as these which spies out the poverty of our land, and to some extent explains the Prime Minister's statement to the effect that our recruiting returns were worse than those of any other belligerent nation in regard to rejections for physical unfitness.

Our local education authorities and our local health authorities, though armed with the necessary powers, have not been carrying out their duty. Even the London County Council, which in many ways has given a lead to all the other authorities in the magnitude and extent of its efforts to alleviate the condition of the children, has lamentably failed in some directions and in none more unaccountably than in developing its open-air school accommodation. "The astonishing fact still remains that London, with 650,000 children, possesses only two ordinary small open-air schools accommodating 210 children."

It is interesting to learn that a Special Aural Board of the Ministry of Pensions has been working in coöperation with officers of the Board of Education in organising the training of soldiers and sailors disabled in the war through deafness and mutism. Twenty-five centres for the teaching of lip-reading have been opened in various parts of the country and the results have as a whole been very satisfactory.

By far the biggest piece of work coming under the heading of special schools, of course, is the care of the mentally subnormal child. The report rightly points out the importance of this class in relation to the activities of the education authorities as a whole. It is fundamentally a part of the larger question of national mental capacity, and not, as is so often assumed, an issue affecting a handful of hopeless children. The war, unfortunately, has rendered it impracticable to secure for the mentally defective child the attention which it was hoped would have resulted from the passing of the Mental Deficiency Act of 1913, and of the Defective and Epileptic Children Act of 1914.

Nevertheless, the work of "ascertainment" under the former Act has been proceeded with in a number of areas, and some local education authorities have consequently been brought face to face with the necessity of considering the requirements of all children mentally subnormal in whatever degree. The "border-line case" keeps on bobbing up, acting as a bridge between the normal and the subnormal, and destroying the "water-tight compartment" method of dealing with the latter, which would be inimical to scientific progress. The present tendency, therefore, is to view the question more as a whole and more in relation to the other activities of the education authority than was formerly the case, and the benefits of the Acts are consequently not confined to the feeble-minded, but affect also the dull and backward, and even the mentally normal child.

These questions have stimulated such inquiries as the recent investigation by Mr. Cyril Burt, psychologist to the London County Council, into the "Distribution and Relations of Educational Abilities." Two broad facts emerge from this inquiry: first, the educational attainments of a "defective" correspond, on an average, to those of a "normal" just one-half his age; secondly, in the whole county of London the number of backward children above the "defective" standard is over 10 per cent. of the whole.

The development of methods of education which will meet the needs of the large class of dull and backward, as well as of the small class of the feeble-minded, is therefore a requirement which should arrest the attention of the authorities. Such methods include the provision of suitable forms of hand work and a more rational system of physical development. In the latter connexion the announcement will be hailed with satisfaction that the Board contemplate the issue of a new edition of their "Syllabus of Physical Education," in which effect will be given to more modern views.

The Future.

The future of school hygiene in this country and the well-being of the child and adolescent population are bound up with the administration of the medical arrangements under the new Education Act. To the section of the report dealing with this Act we, therefore, turn in order to glean the attitude of the Board towards the problems of the future. We are not disappointed. The keynote of the whole report here becomes more than ever insistent. The narrow "bottle of medicine" conception of the purpose of the School Medical Service still held by many persons and authorities is again severely trounced. The ideal of prevention rather than cure is held up as worthy of all acceptation. The Education Act of 1918 is concerned with the physical, as well as the mental, development of the rising generation from the age of 2 years to that of 18. Measures for the promotion of healthy physical development must be preventive as well as remedial. The Act is concerned not only with the provision of facilities for treatment, and special schools for abnormal children, but with the encouragement of measures designed to improve the health, and bring out the physical capacity for development of the whole juvenile population. "What is required is not the devotion of exclusive attention to the diseased child ..... but a broad, carefully considered, and unified system of physical care and development of all children of school age." The foundation of any scheme for attending to the health and physical care of the scholars is defined as a complete system of inspection of all the scholars and reinspection of all found defective.

The dates upon which the sections of the Act come into operation are not all yet fixed, although a number of provisions became operative on August 8th, 1918 (the date of passing of the Act). The Act imposes upon authorities a duty to make arrangements for the treatment of children educated in public elementary schools, thus making this function in future compulsory instead of voluntary, but the section is not yet in operation. It imposes a duty upon authorities to provide for medical inspection in secondary and continuation schools, and the power is given to provide facilities for treatment; this section is in operation except so far as it imposes a duty.

It is important to note that the Act prohibits the establishment of a general service of domiciliary treatment by medical practitioners, but provides that in making arrangements for treatment an authority shall consider how far they can avail themselves of the services of private medical prac-

titioners. The Act makes it the duty of an education authority to ascertain what children within their area are physically defective or epileptic within the legal definition, and also to make provision for their education between the ages of 7 and 16, but this section is not yet in operation.

Several sections of the Act which are not yet in operation deal fairly drastically with the employment of children o school age, but it is interesting to note that a section whic is already in operation empowers the local authority t prohibit or restrict any employment of a child which, as result of a report by the school medical officer, or otherwis they are satisfied is prejudicial to his health or physic development, or which renders him unfit to obtain pro benefit from his education. The clauses of the Act empow ing local authorities to establish or to aid nursery schools children between 2 and 5 are already in operation.

The final paragraph of the section of the report dea with the Act forms such an admirable epitome of Sir Ge Newman's conclusions, ideals, and aspirations that cannot do better than quote it in extenso.

> The fundamental purpose of the new Act is "the progressive de ment and comprehensive organisation of education" available persons capable of profiting thereby. It is indisputable th primary factor in such an organisation must be the physical fact system of education, however perfect, must fail if the physi mental condition of the person to be educated be not healthy res and alert. Indeed, the association between physique and educ even closer, for the education and development of the young largely a question of bodily nature and nurture. Not only the body be sound and unimpaired by defect or deformity, but its ning and development is an integral, essential, and vital part of true educa ion. The local education authorities throughout Eng and Wales are now in possession of an adequate and comprehensi strument for achieving these great national ends. The ines im good which they have accomplished in ten years, with meagre and ewhat indifferent machinery, affords good promise of their wise and seeing use of the new and enlarged opportunity, at the door of wh they now stand.

We devoutly re-echo Sir George Newman's word and we should like to share his confidence to the full, ut the supineness of the local education authorities in t past, as revealed by his own report, raises grave doubts.

URBAN VITAL STATISTICS.

(Week ended Dec. 14th, 1918.)

English and Welsh Towns.—In the 96 English and ish towns, with an aggregate civil population estimated at 16,500,0 ersons, the annual rate of mortality was 20·2, against 36·5 and 2 per 1000 in the two preceding weeks. In London, with a popu lon slightly exceeding 4,000,000 persons, the death-rate was 18·2, 7·8 per 1000 below that recorded in the previous week; among remaining towns the rates ranged from 7·4 in Bournemouth, 7·9 Walthamstow and in Oxford, and 10·0 in Cambridge, to 38·6 in ston, 34·7 in St. Helens, 42·1 in South Shields, 42·8 in Grimsby, 48·9 Barnsley, and 54·1 in Sunderland. The principal epidemic diseases ed 148 deaths, which corresponded to an annual rate of 0·5 per 100 and included 48 from diphtheria, 47 from infantile diarrhœa, 23 from ooping-cough, 14 from measles, 12 from scarlet fever, and 4 fro enteric fever. The deaths from influenza numbered 1885, against 74 in the preceding week, and included 322 in London, 164 in Birmingham, 111 in Manchester, 82 in Sunderland, 53 in Nottingham, and in Liverpool. The 1089 cases of scarlet fever and 1017 of diphthe a under treatment in the Metropolitan Asylums Hospitals and t London Fever Hospital were 10 and 11 below the respective numbs remaining at the end of the previous week; there were also 2 ces of small-pox under treatment. The causes of 50 deaths in t 96 towns were uncertified, of which 8 were registered in Birmingha, and 4 each in Southend-on-Sea, Hull Stockton-on-Tees, and Gateshad.

Irish Towns.—The 168 deaths in Dublin corresponded to an annual rate of 22·0, or 0·5 per 1000 below that recorde in the previous week, and included 24 from influenza, 2 from infants diarrhœa and 1 each from scarlet fever and whooping-cough. The 1 deaths in Belfast were equal to a rate of 24·7 per 1000, and incided 1 each from whooping-cough, diphtheria, and infantile diarrhœ

METROPOLITAN HOSPITAL SUNDAY FUND.—At the annual meeting held at the Mansion House on Dec. 20th, the Lord Mayor presiding, ne members of the council were re-elected, with the ddition of the Rev. E. Marling Roberts, the Rev. W G. Pennyman, Dr. Jowett, and Sir Charles Hanson o fill vacancies. Hospital Sunday, 1919, was fixed for une 22nd. The report stated that the total collection fr 1918 (the forty-sixth) had amounted to £92,055, an increase of over £15,000 as compared with 1917. This increase, which had exceeded the highest previous record, had enabl d the council to distribute a sum of over £85,000 amon the hospitals and medical charities of London, being £15,000 more than any previous distribution. The collections in the churches amounted to £43,077, or £5739 more than in 1917, while the donations were £13,259, showing an increase of £5106. The fund received a donation of £5000 from the American Red Cross in recognition of the work done by London hospitals for the Allied wounded.

"Audi alteram partem."

TRENCH FEVER CACHEXIA.

To the Editor of THE LANCET.

SIR,—The article by Colonel R. D. Rudolf, C A.M.C., on French Fever Cachexia, in THE LANCET of Dec. 14th, draws attention to a condition which has been recognised in France for the last two years. It is interesting to have, from an observer in England, a confirmation of many of the opinions and conclusions arrived at from seeing cases in the earlier stages, and the subject is of such importance for the future that it cannot be too widely known and discussed. The literature of trench fever has been voluminous, but has mainly been directed towards a description of the types of the disease as seen in the earlier stages, or to a discussion of the etiology and the infectivity of the disease, whilst little attention has been paid to the later stages.

Everybody is now well acquainted with the common types of the disease—the short, the long, and that with a prolonged initial fever. The work of the American Red Cross Commission proved that these are all simply variations of expression of a common infection. In addition, many of us had recognised, as far back as 1916, a type which we called the "smouldering" type, in which the patient complained of debility, weakness, irregular pains, &c. This was regarded, not as a distinct type, but rather as a condition following on after an infection from which the man had apparently recovered completely, and yet the infection "smouldered" on or reappeared after a period of latency. The parallel to malarial cachexia which Colonel Rudolf draws is an apt one, and evidently the cases which he describes are similar to those which have been a source of much perplexity in France.

The parallel may be carried even further, for trench fever apparently has the power to remain latent and flare up again, more particularly after any trauma. It was no uncommon experience to notice this recrudescence in the surgical wards, as many of the wounded commenced within a few days of being injured a typical febrile attack which could not be accounted for by the condition of their wounds, and cross-examination then elicited a history of previous trench fever. Hard work, physical or mental, over a prolonged period, also appeared to have the power of re-kindling the disease. As to how long this latency is maintained, we have as yet no accurate knowledge, but cases have now been followed for nearly four years, in which recrudescences of diminishing virulence have appeared, and in which a diminution of vigour has been noted throughout.

A recognition of these facts will make for more accurate diagnosis in the Army, and will largely eliminate that popular diagnosis of "myalgia" Captain F. B. Chevasse and Captain Marr have independently worked at this point, taking groups of cases labelled "Myalgia," and trying to establish a correct diagnosis. The former considered that some 43 per cent. were in reality suffering from trench fever, and the latter put the figure at nearly 70 per cent. My own observations, made on a less exact but a wider scale, by "sampling" admissions in many areas, would indicate that at least 70 per cent. and probably nearly 80 per cent. of the "myalgias" were in reality suffering from trench fever. The majority of the cases included in these observations were examples of the cachectic period of the disease.

A correct diagnosis may not be easy in the late stages when cases are seen in English hospitals or after discharge from the Army. A careful consideration of the history will often furnish the clue. Colonel Rudolf has pointed out the value of the temperature chart, which we learned to rely on very largely. So much was this the case that in order to obtain a record from as early as possible a moment all field ambulances in France were supplied with a rubber stamp giving an impression of a six days' chart for use on the field medical card. The oscillation of the temperature, giving a diurnal swing of two or more degrees, appears to be just as important as an actual rise above the normal. Other points to look for are a quickened pulse, maintained in the eighties, tremor of hands and tongue, small patches of yellow fur on the tongue, and the presence of spots of local tenderness on palpating over the muscular insertions and indicative of a persistence of that fibrous involvement which

s characteristic of the earlier stages. I am interested to note that Colonel Rudolf finds persistence of splenic enlargement, as that had not been determined in France. The presence of a relative lymphocytosis, mainly of the large lymphocytes, may be of value in the doubtful case.

Practitioners will in the coming future be faced frequently with the diagnosis and the treatment of these cases, and when it is remembered that probably a fifth of the cases of disease, as apart from wounds, in the armies in France has been caused by trench fever, the numerical importance of the question is obvious, especially as we do not yet know for how long this liability to recurrence will be maintained.

I am, Sir, yours faithfully,

A. BERTRAM SOLTAU,
Colonel, A.M.S.

Dec. 17th, 1918.

PHTHISIS IN FACTORY AND WORKSHOP.

To the Editor of THE LANCET.

SIR,—Dr. M. F. Boulenger (THE LANCET, Dec. 14th) apparently considers "hereditary tuberculosis" as the cause of tubercle in abstainers and alcoholism as the cause of it in drunkards. In the interests of clarity it would be well if he explained what "hereditary" means in this connexion. I understand "congenital tuberculosis," "congenital syphilis," "congenital ophthalmia," "congenital small-pox," and the like. These expressions denote that the micro-organisms of disease infected the child while it was yet within the mother's body. But what does "hereditary" tuberculosis imply? Would Dr. Boulenger class a bullet that had passed through the mother and lodged in the child as a hereditary bullet? Bullets and bacilli alike are foreign bodies. As far as the evidence goes, congenital tuberculosis, unlike congenital syphilis and ophthalmia, is very rare.

In tuberculosis, as in all other developments, two factors are concerned, nature (heritage, susceptibility, predisposition) and nurture (*terrain*, environment). Both the susceptibility and the environment vary enormously in relation to individuals and races. Thus, some Englishmen, and all Polynesians, are very susceptible; most Englishmen but no Polynesians are able to survive in the slums of great cities; practically no Englishman contracts the disease in Polynesia where it is exterminating the native. The rule that "Every human race is resistant to every lethal and prevalent human disease in proportion to the length and severity of its past experience of that disease" applies to tuberculosis. Thus, Jews, who have 20 centuries of urban life behind them, are more resistant than Englishmen, who are more resistant than Scottish Highlanders, who are more resistant than American negroes, who are more resistant than African negroes, who are more resistant than Polynesians. The rule itself is explainable only on the supposition that powers of resistance (which are not foreign bodies) are inheritable, and that each lethal disease weeds out the weak against *itself*, leaving the race to the strong.

The cause of tuberculosis is the *Bacillus tuberculosis*. All conditions which favour the survival and concentration of the bacilli and their passage to susceptible persons—e.g., ill-lighted, ill-ventilated, and crowded buildings—conduce to the spread of the disease. So, also, do all conditions—excessive drinking, among others—which depress the vitality of human beings. I do not know whether statistics exist, but I venture to predict that women industrial workers—because they work in crowds—suffer more from the disease than women engaged in house duties. Dr. Boulenger insists that the "essential cause" of adult tuberculosis is alcoholism, and so explains the fact that male industrial workers suffer more than their wives whose environment he regards as worse. But do not these men sleep in their own homes? And was alcoholism the cause of the prevalence of the disease in convents, jails, and Pacific islands, and the essential cause of most of the many deaths among the men and women we have each known? Of course, excessive drinking is sometimes a contributory cause. And, of course, excessive drinking is in itself a tremendous evil. But intemperance in argument is not likely to cure intemperance in drinking. The case of vaccination should be borne in mind. Originally medical men claimed that vaccination endowed the individual with permanent immunity to small-pox. As a fact it confers only temporary immunity, which, however, is sufficient, for vaccination, repeated when necessary, abolishes small-pox. But to this day its opponents rely on disproof of the original and long-abandoned claim as a principal weapon for discrediting not merely vaccination, but all protective inoculation. Excessive claims, even when made in such a good cause as temperance, tend to meet the proverbial fate of vaulting ambition which overleaps itself.

I am, Sir, yours faithfully,

Southsea, Dec. 15th, 1918. G. ARCHDALL REID.

DISPENSARY SUPERVISION IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I have noted with satisfaction the interest which my article (THE LANCET, Oct. 26th) appears to have aroused, because I believe that the favourable opinion of the Interdepartmental Committee on Tuberculosis as to the value of the treatment under close supervision is justified by more recent experience upon a large scale. Of course, like all other antituberculosis measures it has its limitations, but this is no argument against its utilisation in the large number of cases where it may be satisfactorily applied, if the requisite trouble be taken.

The first fact that has to be faced is that so long as patients are solely under the care of general practitioners, close supervision of their hygienic routine is seldom exercised in working-class practice, and, as a matter of fact, on the tuberculosis officers' or dispensary nurses' first visits in many cases there is often little visible evidence of any instructions having been given to patients as required by the Tuberculosis Regulations. Even when such instructions have been given there is apparently nothing in the Regulations requiring a panel doctor to see that they are actually followed. The tuberculosis dispensary organisation has thus a great field of activity, and in the administrative county of Lancashire we are doing our best to make full use of our opportunities. Apart from the personal efforts of the dispensary staff in giving simple hygienic instructions and in getting them carried out voluntarily, it has been possible in a large number of cases indirectly to aid the work by means of the voluntary care committees, which assist patients on the understanding that the instructions given are properly carried out. The six care committees in my area have expended in 1917 over £1000.

The knowledge, too, that certain benefits are obtainable from Approved Societies in the case of insured persons and from the Ministry of Pensions in the case of discharged sailors and soldiers conditionally upon the treatment being properly carried out is also of use in certain cases.

Perhaps I did not make it quite clear in my article that patients with active disease receive domiciliary treatment from general practitioners, and that the dispensary organisation works in close association with them. In this way patients obtain the advantages of both agencies.

With regard to the visits of the dispensary nurses, which are always paid without previous notice, it must be remembered that many of the cases were quiescent or arrested. These do not, of course, require frequent visiting, so that it has been possible for the more advanced cases to receive more frequent visiting. The number of visits paid might with advantage be increased, and at the end of the war it is hoped to augment the staff of nurses and thus pursue more intensively the dispensary supervision.

I should have done better to have used the term "satisfactory isolation" or "sufficiently complete isolation," instead of "complete isolation." In 1917 I obtained satisfactory isolation in 70 per cent. of 1615 cases of pulmonary tuberculosis. As a matter of fact, I do not think that "complete" isolation need be aimed at, since it is now generally recognised that infection must usually be massive to be the potent factor. We are all exposed to the tubercle bacillus in a greater or less degree, and although there is evidence that 97 per cent. of persons are actually infected the dose is insufficient in most cases to break down the resistance. If the instructions as to disposal of sputum, &c., are reasonably followed the risks of infection should be slight. In my opinion the greatest danger from infective cases at home arises from the large, untapped reservoir of unnotified cases, to which Dr. G. Lissant Cox referred in his recent letter. So long as large numbers of cases die either unnotified or only notified shortly before death the control of tuberculosis must necessarily be imperfect, and for this it is not fair to blame the dispensaries.

It is a great advantage if patients can receive two or three months' institutional treatment soon after they come under

treatment, while there is a residuum of advanced cases for whom permanent removal to a suitable hospital is desirable, owing to the impossibility of securing adequate nursing and isolation at home. The compulsory powers of removal possessed by a few county boroughs ought, in my opinion, to be given to all county and county borough councils.

In conclusion, I submit that even in the worst cases under dispensary supervision the home conditions are superior to those usually found where this is absent, and that the results would be even better were sufficient funds available to supplement the resources of the poorer families. It is not improbable that the work of the voluntary care committees will have to be taken over by the dispensary organisations and become a national charge.

I am, Sir, yours faithfully,
GEORGE JESSEL,
Dec. 18th, 1918. Tuberculosis Officer, Lancashire County Council.

LADY ROBERTS' FIELD GLASS FUND: RETURN OF GLASSES NOW ASKED FOR.

To the Editor of THE LANCET.

SIR,—May I, through the hospitality of your columns, ask all officers and others who have received glasses or telescopes on loan through my Fund to send them back to me now for return to their owners. All instruments lent through my Fund bear the letters N.S.L. (National Service League), followed by a letter and a number. I should be glad if officers and others returning glasses would enclose in the case a note of acknowledgment for the owner.

I wish to record my gratitude, not only to the public for the munificent loan of 30,000 glasses, but also to the press for the valued help which it has given this undertaking.

The address for glasses and correspondence is the Manager, Lady Roberts' Field Glass Fund, 64, Victoria-street, Westminster, S.W. 1.

I am, Sir, yours faithfully,
Dec. 19th, 1918. ROBERTS.

THE PRACTICE OF THE ABSENTEE.

To the Editor of THE LANCET.

SIR,—It is gratifying to see that money is still being subscribed to the Belgian Doctors' and Pharmacists' Relief Fund. This is as it should be, but it is of interest in connexion with Sir Watson Cheyne's proposal to lend money to medical men whose practices have been filched from them owing to their absence at the front. These men have been as much injured by their professional brethren as their Belgian colleagues have been by the Hun. Yet the proposition of Sir Watson Cheyne savours more of the spirit of the Jewish moneylender than anything else.

Would it be too much to expect that the British doctors should meet with as much sympathy and help as the Belgian? Many of us have been away on active service for over four years, having "willingly" given up "all" in answer to the pitiful cries of our sick, wounded, and dying fellow countrymen. Surely, then, we are not to be expected to return home and forced to beg from our professional brethren who have stayed at home. All the medical men in this theatre of operations with whom I have discussed Sir Watson Cheyne's proposals are strongly opposed to it, as it is adding insult to injury.

It is now suggested by Sir Watson Cheyne that some of the ill-gotten gains of the medical pilferers should be advanced on loan at interest to their victims.

I am, Sir, yours faithfully,
Dec. 6th, 1918. MAJOR, R.A.M.C. (T.C.)

THE LANCET, VOL II., 1918: THE INDEX.

THE Index and Title-page to the volume of THE LANCET which is completed with the issue of to-day is in preparation. Owing to the continued shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a *post-card* which is more convenient for filing purposes than a letter) to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

The War and After.

THE CASUALTY LIST.

THE names of the following medical officers appear among the casualties announced since our last issue:—

Died.

Surg.-Lieut.-Cdr. M. H. Langford, D.S.O., R.N., was a student at Middlesex Hospital, London, and qualified in 1909. He thereupon joined the Royal Navy and was serving on the *Inflexible* both when she took part in the action against the German squadron off the Falkland Islands and also when she struck a mine in the Dardanelles. It was in connexion with this latter incident that he was awarded the D.S.O. He died at Dar-es-Salaam of influenza.

Capt. J. V. Duffy, R.A.M.C., qualified at Glasgow in 1914, and joined up shortly afterwards.

Wounded.

Capt. R. H. Jones, R.A.M.C., attached Worcester Regiment.

OBITUARY OF THE WAR.

ROBERT ERNEST LEE, M.D. T.C.D.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain R. E. Lee, who lost his life through the sinking of R.M.S. *Leinster* on Oct. 10th at the age of 35 years, was the second surviving son of Edward Lee, J.P., Blackrock, co. Dublin. Educated at Trinity College, Dublin, he graduated in medicine in 1910, and obtained the M.D. degree in the following year. He was then house surgeon to Bootle Hospital, Liverpool, for two years, and resident medical officer of the Royal Hospital for Incurables, Donnybrook, Dublin, 1912–13. Before the outbreak of war he had been on a sea voyage as medical officer on one of the Holt Line ships. When war was declared he joined the R.A.M.C., and served in France from January, 1915, until he met his death on returning to duty after 14 days' leave.

NOEL JAMES ALLAN, M.B., CH B. LIVERP.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain N. J. Allan, who died of burns on Oct. 18th in Mesopotamia at the age of 32 years, was second son of Dr. J. H. Allan, of Liverpool. He was educated at St. Francis Xavier's College, where he was distinguished in mathematics and chemistry. After leaving school he qualified in pharmacy, but later decided to take up medicine, and entered the University of Liverpool. In the course of his medical studies he gained the Kanthack medal in pathology, the senior Lyons-Jones scholarship, and the Derby prize for clinical medicine, and he graduated with honours in 1916. He held for a short time the posts of house surgeon and house physician at the Royal Infirmary, and early in 1917 joined the R.A.M.C. and served continuously in the East until his death.

MAURICE WILLIAM HOLT MILES, M.B. LOND.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain M. W. H. Miles, who died on Nov. 25th at the age of 25 years, was son of William Miles, of Streatham. Educated at Littlestone and Merchant Taylors' School, where he obtained a scholarship for St. Thomas's Hospital, he volunteered for service at the commencement of the war and was sent to France, and afterwards to India, Egypt, and the Dardanelles. He was ordered home to qualify, took the diploma of the Conjoint Board in 1917, and became house physician at St. Thomas's Hospital before joining the R.A.M.C. His health was already considerably undermined by malaria and dysentery. Invalided out of the Army about two months ago, he again returned to St. Thomas's Hospital, whence he recently took the M.B. degree. His death was due to pneumonia following influenza.

JOHN EDWARD HODGSON, M.R.C.S. ENG., D.P.H.,

LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel J. E. Hodgson, who died on Nov. 5th at Dédéagatch while with the British Salonika Force, was eldest son of the late Caleb Hodgson, of Carlisle, and stepson of the late Colonel J. J. Durant. He was educated at Grosvenor House School, Carlisle, and Owens College, Manchester, and took the diplomas of the Conjoint Board in 1898, and the D.P.H. Lond. in 1913. After acting as resident clinical assistant at the Barnes Convalescent Hospital, Cheadle, he entered the R.A.M.C. as Lieutenant in January, 1899, and during 1899–1900 served in the South African War. He took part in the advance on Kimberley, including the actions at Belmont, Enslin, Modder River, and Magersfontein, and was awarded the Queen's medal with two clasps. After serving at Dover for atime he proceeded to India in 1901, and was appointed staff surgeon, Fort William, Calcutta, which appointment he held for three and a half years, finishing his tour of foreign service at Ranikhet. He was gazetted captain in January, 1902, major in 1910, and lieutenant-colonel in 1915. After serving over three years in the London district Colonel Hodgson was appointed sanitary specialist, Northern Command, in January, 1914, and in August, 1916, was appointed A.D.M.S., 12th Corps, Salonika, and there served, with only one short leave, until his death, which was due to pneumonia following on influenza. In December, 1917, he was mentioned in despatches. Colonel Hodgson leaves a widow and one son.

Captain (acting Major) WINFRED SMYTH MACDONNELL, C.A.M.C., who died on Nov. 15th, aged 29 years, was a native of Port Hood, Nova Scotia, and graduated in medicine at Dalhousie University, Halifax, N.S., in 1910. He served for seven months in the Royal Navy, with the R.A.M.C. in France for one year, and was appointed to the C.A.M.C. in August, 1916. He was attached to the Duchess of Connaught's Hospital, Taplow, until last September, when he was transferred to the London area and appointed D.A.D.M.S.

JAMES GASTON, M.B., B.S. R.U.I.,

MILITARY CROSS;
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain J. Gaston, who died of wounds received in France on Nov. 5th, was eldest son of Andrew Gaston, Carabeg, co. Antrim. Educated at Ballymena Academy and Queen's College, Belfast, he graduated at the Royal University of Ireland, and when war broke out was engaged in an extensive practice in Durham. He joined the R.A.M.C. in December, 1914, and went to France in March, 1915. After serving with a West Riding field ambulance he was attached to the 5th K.O.Y.L.I. as battalion medical officer. He was wounded in September, 1916, and after recovering from his wounds he again went to France in January, 1917, and was attached to the Suffolk Regiment. In the following April he was awarded the Military Cross for conspicuous bravery in the field. Captain Gaston was known to his chiefs as a brave and courageous officer and to his colleagues as an agreeable companion.

THE HONOURS LIST.

The following awards to medical officers are announced:—

K.C.I.E.—Lt.-Gen. T. J. O'Donnell, C.B., D.S.O., R.A.M.C., Director of Medical Services, India.

C.I.E.—Col. H. J. Barratt, R.A.M.C. (retired), Assistant Director of Medical Services, Meerut Division; Col. S. C. Philson, R.A.M.C. (retired), Assistant Director of Medical Services, Karachi Brigade.

C.B.E.—Col. W. Molesworth, C.I.E., V.H.S., I.M.S.; Col. A. W. Sheen, A.M.S.(T.F.).

O.B.E.—Maj. A. E. Walter, I.M.S.; Maj. (acting Lt.-Col.) P. J. Van Collier, S. African M.C.; Lt.-Col. G. M. De Kock, S. African M.C.; Lt.-Col. J. R. McGregor, S. African M.C.; Lt.-Col. (Hon. Col.) H. T. Mursell, S. African M.C.

MENTIONED IN DESPATCHES.

In a despatch received from the Commander-in-Chief, East African Force, dated Sept. 30th, 1918, the following references to the medical services appear:—

Great efforts were made to keep the hospital accommodation and all health and sanitary conditions up to the high standard which the Pike Commission and the visit of Major-General Scott indicated as being aimed at in other theatres. The result has been highly gratifying. The sick-rate among the troops, and particularly among Europeans, must always be heavy in a tropical climate, but it is satisfactory to know that everything possible has been done to alleviate suffering and restore health. Among the porters there was an enormous improvement both in the sick and death rates; in fact, the latter is now very little in excess of peace rates.

A school for training natives as hospital attendants and dressers was started at Dar-es-Salaam, and has proved an unqualified success, and great credit is due to the officers responsible for it. After the completion of their military service the natives thus trained should prove a distinct asset to their respective Protectorates.

The native medical corps recruited in Uganda was of special service to us.

Colonel G. W. Tate, C.M.G., D.S.O., M.B., Army Medical Service, deserves great credit for the very efficient manner in which the work of the Medical Services has been carried out, in spite of the difficulties inseparable from active service in a tropical country.

"Silver Badge" calls attention to the inadequate scale of remuneration offered by the War Office to certain medical officers of war hospitals. The operative work in these hospitals may, he says, be carried out by three classes of surgeons: (1) men with temporary commissions; (2) *à la suite* staff with territorial rank as part-timers; (3) part-timers with no commission. The first two classes are paid according to their rank, as a rule of major or lieutenant-colonel, but the third class receives 22*s*. 6*d*. per day, attending only when summoned by the officer in charge of the hospital, every day for which he is not called resulting in a credit of 22*s*. 6*d*. to the hospital. In this way "Silver Badge" claims that the surgeon loses touch with the cases upon which he has operated, while his work is crowded into two or three days a week. He considers that part-time surgeons should be paid an adequate remuneration for their work, and on a monthly basis.

Medical News.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful:—

M.D. EXAMINATION.

Branch I., Medicine.—Louis Abel Celestin, Univ. Coll. Hosp.; and Eric Clarence Spaar, private study.

Branch IV., Midwifery and Diseases of Women.—Grace Stapleton, Lond. Sch. of Med. for Women.

M.S. EXAMINATION.

Branch I., Surgery.—Stanley Ritson, King's Coll. and King's Coll. Hosp.

UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful:—

FINAL M.B. AND CH.B.

N. H. Davison, Bryan Walley, and Ethel D. Willis.

Forensic Medicine.—May Ashburner, Mary S. Jones, J. N. Laing, and Efime Ratner.

THIRD M.B. AND CH.B. EXAMINATION.

General Pathology and Morbid Anatomy.—Samuel Adler, May Blakiston, J. W. Crawshaw, K. V. Drakin, F. R. Ferguson, Evelyn A. Garnett, E. M. Greaves, G. E. Hayward, Sylvia K. Hickson, J. B. Higgins, F. S. Horrocks, Irma M. C. Jehansart, F. C. Jones, W. E. Mason (with distinction), Doris B. Norman, E. R. Ormerod, Emily M. Peach, Harry Rosenthal, Gerald Sheehan (with distinction), Constance Snowdon, Annie E. Somerford, G. L. Taylor (with distinction), H. W. Taylor, Henry Tomlinson, Mary I Turner, F. A. van Coller, Raymond Williamson (with distinction), and J. B. Wright.

DIPLOMA IN DENTISTRY (*Final Examination*).

A. D. Bleakley and Bertram Wilkinson.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on Dec. 18th the following candidates, having passed the requisite examinations between Sept. 30th and Oct. 2nd, were admitted Fellows:—

John Ellison, Robert Joseph English, James Burnett Hogarth, Robert Lyle Hutton, Millen Alexander Nickle, Ibrahim Abdell Razzak, James Ness MacBean Ross, Augustus George Stewart, David Laurence Tate, William Robert Tutt, and Wilson Tyson.

THE amount which the League of Mercy has contributed this year to King Edward's Hospital Fund for London was stated by Lord Farquhar at the annual meeting of the League on Dec. 20th, to be £16,000, in addition to £3392 granted to extra-metropolitan hospitals.

INSTITUTE OF MASSAGE AND REMEDIAL GYMNASTICS.—The annual meeting of this institute was held at the Chartered Accountants' Hall, Manchester, on Dec. 17th, Sir William Milligan, chairman of the executive, being in the chair. He presented a report of the working of the institute during the past 12 months. The institute originated in 1914 and was incorporated in 1916. The negotiations with the Incorporated Society of Trained Masseuses had led to the drafting of a charter which might now be taken as the settled views of the two bodies. This charter was now complete and simply awaited revision by counsel, after which it would be submitted to the Privy Council, and, if accepted by them, would become the charter of a new society arising out of the amalgamation, representative of massage throughout the country. In the meantime the examinations and other activities of the institute had been in abeyance. The charter, when completed, would yield a strong body with a council elected by postal ballot of the whole of the members. On the proposal of Dr. A. E. Barclay, honorary secretary, it was unanimously decided to accept the provisions as laid down in the draft charter.

INFLUENZA IN SOUTH AFRICA.—A South African correspondent, writing on Oct. 29th, says: The influenza epidemic in South Africa has been responsible for about 50,000 deaths during the first month after it broke out, about 10,000 occurring among Europeans, and, as in England, healthy individuals in the prime of life have been most often attacked. Apparently introduced from Europe, it has been attributed to returning South African labour battalions, trench fever, German gas, or deliberate Hun propaganda. The preventive measures which have been taken include the use of gargles, mouth-washes and nasal douches of salt and water, &c., as well as inoculation, which in some places appears to have been of use. In most of the towns drastic precautionary measures have been adopted, including closing of schools, places of entertainment and churches, market halls and auction rooms, as well as the prohibition of public gatherings. The native is an important factor in transmitting infection, and the epidemic is in consequence subsiding more quickly in the towns than in the villages and country. Pneumonia is the usual cause of death. The Cape Peninsula has been severely attacked and the mortality has been high, and, as in other parts of the Union, the railway, postal, and tramway staffs were greatly depleted. As far as the towns are concerned, Cape Town, Kimberley, Johannesburg, and Bloemfontein have suffered most from the scourge.

THE SERVICES.

ARMY MEDICAL SERVICE.

TERRITORIAL FORCE.

Col. W. Coates, C.B. (Retired List, A.M.S., T.F.), to be Colonel.

ROYAL ARMY MEDICAL CORPS.

The undermentioned relinquish the acting rank of Lieutenant-Colonel on re-posting: Major L. V. Thurston; Capts. G. F. Rudkin, R. E. Todd.

To be acting Lieutenant Colonels whilst in command of a Medical Unit: Temp. Capt. (acting Major) H. S. Davidson; Majors H. Harding, C. J. Wyatt, C. W. O'Brien.

Temp. Major F. R. S. Cosens (Lieut.-Col., Devon Regt. T.F.), to be temporary Lieutenant-Colonel.

Temp. Capt. J. Cunningham to be acting Major whilst specially employed.

The undermentioned relinquish the acting rank of Major: Capt. O. W. McSheehy; Temp. Capts. J. F. R. Gairdner, H. C. Wilson, R. B. Rutherford, J. H. Hebb.

Temp. Capts. to be acting Majors: A. A. Miller, M. W. Baker, F. B. Chavasse, J. F. McLay, O. E. Finch, F. R. Fraser, H. L. Tidy, W. F. Box, C. S. Dodson, T. Martin, H. D. Ledward, J. A. Jones, E. T. Willans.

V. H. Kazanjian to be temporary Honorary Major whilst serving with No. 22 General Hospital (Harvard Unit).

Capt. (acting Major) W. B. Allen, V.C., from R.A.M.C. (T.F.), to be Captain.

Lieutenants (temporary Captains) to be Captains: E. Jamieson, J. E. Brooks.

The undermentioned late temporary Captains retain the rank of Captain: R. A. Jones, T. E. Parker.

M. Cohen, late temporary Captain, is granted the rank of Captain.

To be temporary Captains: E. Ashby, F. S. Collard.

Temp. Hon. Lieuts. J. M. Bremner and T. C. Bost to be temporary honorary Captains.

To be temporary Lieutenants: A. A. Angelis, J. T. Rearden, W. J. Lord, H. Caird, J. Grimson, C. L. Lapper, C. J. E. Edmonds, N. J. McCaskie, R. Hamer, J. V. Rees, J. Stewart.

M. M. Stevens to be temporary honorary Lieutenant whilst serving with No. 22 General Hospital (Harvard Unit).

Officers relinquishing their commissions: Temp. Lieut.-Col. F. Romer (on grounds of ill-health, and is granted permission to retain his rank); Temp. Capts. D. A. Stewart, R. V. Steele, F. I. Dawson, W. M. G. Guinness, H. F. Powell, W. M. Penny, G. H. Rodolph (on account of ill-health, and is granted the rank of Lieutenant). W. M. Thomson, S. A. Bull (and is granted permission to retain his rank). E. W. Toulmin (on account of ill-health and is granted permission to retain his rank), S. S. King, A. C. Fleming, J. W. O'Farrell, J. F. Powell, W. L. O'Neill, J. D. Ferguson, W. L. Clements, H. C. Wilson, A. Campbell, J. S. Clark, R. B. Rutherford, F. Wilkinson, T. H. Ravenhill, J. C. Wadmore, E. W. Kirk. G. L. N. Miles and F. M. Longson (on account of ill-health, and to retain the rank of Captain), W. H. T. Jones, E. W. Goble, R. J. Duthie, J. Maguire, G. L. Irwin, W. S. Hall, F. G. Wrigley, A. M. Roome, A. R. F. Hay, G. H. G. Davie, L. C. W. Cane, G. E Thornton, H. Freeth, B. B. Sapwell, R. S. Berry; Temp. Hon. Capt. T. C. Bost; Temp. Lieuts. C. W. Branson, J. Shaw, H G. Browning, F. A. Hadden (on account of ill-health contracted on active service, and is granted permission to retain his rank), S. McClure, T. McLaren, A. Macintyre.

Canadian Army Medical Corps.

Temp. Major T. A. Lomer, D.S.O., to command a Field Ambulance, and to be acting Lieutenant-Colonel whilst so employed.

Temporary Captains to be acting Majors whilst employed at a Field Ambulance: W. J. MacKenzie, F. F. Dunham.

SPECIAL RESERVE OF OFFICERS.

Capt. R. Magill, D.S.O., relinquishes the acting rank of Lieutenant-Colonel, and reverts to the acting rank of Major.

Capt. W. M. Biden to be acting Major.

Captains relinquishing the acting rank of Major on re-posting: J. W. Gray, R. MacKinnon.

W. V. Robinson, from University of London Contingent, O.T.C., to be Lieutenant.

TERRITORIAL FORCE.

General List.—The undermentioned officers to be acting Majors whilst specially employed: Capts. W. E. Lee, D. A. R. Haddon, H. Shield.

Capts. (acting Majors) J. W. Craven, R. D. Moore, M.C., and A. W. Stott relinquish their acting rank on ceasing to be specially employed.

Capt. J. W. Scott to be acting Major whilst specially employed.

Capt. (acting Major) A. H. Horsfall, from 2nd Northern General Hospital, to be Captain.

Capt. A. H. Horsfall to be Major.

Capt. H. G. W. Dawson to be acting Major, with precedence.

2nd Southern General Hospital: Capt. C. A. Moore to be acting Major whilst specially employed and to remain seconded.

2nd Western General Hospital: Capt. H. Buck to be acting Major whilst specially employed and to remain seconded.

3rd Scottish General Hospital: Major H. Rutherfurd, M.B., is seconded for duty with a General Hospital.

2nd London Sanitary Company: Lieut. A. H. Hasnip to be Captain.

3rd Southern General Hospital: Capt. J. F. Robinson is restored to the establishment.

Sanitary Service: Capt. C. M. Fegen to be acting Major.

2nd London Sanitary Company: Capt. R. T. F. Barnett relinquishes his commission on account of ill-health contracted on active service, and retains the rank of Captain.

Attached to Units other than Medical Units.—Capt. (acting Major) J. W. Scott relinquishes his acting rank on ceasing to be specially employed.

ROYAL AIR FORCE.

Medical Branch.—W. G. L. Wambeek, late temporary Captain, R.A.M.C., is granted a temporary commission as Captain.

F. N. V. Dyer, J. Paxton, and J. Souter (late temporary Surgeons, R.N.) are granted temporary commissions as Captains.

J. B. Barnett and C. H. Young are granted temporary commissions as Lieutenants.

Notes, Short Comments, and Answers to Correspondents.

COLONIAL HEALTH REPORTS.

Hong-Kong.—The estimated population at the middle of 1917 was 535,100. The corrected birth-rate for the year was 6·9 per 1000 among the Chinese community and 20·8 per 1000 among the non-Chinese. The death-rate was 23·7 per 1000 among the Chinese community and 14·0 among the non-Chinese. The number of deaths from malaria (416) showed an increase on the previous year. The deaths of Chinese from this cause in the city of Victoria numbered 185 out of a population of 280,700. The deaths from plague numbered 35, as compared with 39 in 1916. Small-pox deaths numbered 549, all Chinese with the exception of 3 Portuguese and 1 each British, Filipino, and Japanese. There were 2248 deaths from respiratory diseases, 34 of these being among the non-Chinese community. Pulmonary tuberculosis claimed 859 Chinese and 18 non-Chinese victims, whilst other forms of tuberculosis represented an additional 616 deaths, making a total of 1493, or 14·3 per cent. of the total deaths among the community. Beri-beri was responsible for 654 deaths, as compared with 517 during 1916 and 398 in 1915. During the past few years circulars have been distributed to all large employers of coolie labour calling their attention to the fact that beri-beri is produced by the consumption of white rice as the staple article of diet without a sufficiency of other foods, and advising that beans should be supplied with the rice when fresh meat or fresh fish cannot be afforded. At the Civil Hospital 3292 in-patients and 13,065 out-patients were treated during 1917. 361 cases of malarial fever were admitted, as against 360 in 1916 and 384 in 1915, but the total cases of malaria for all hospitals showed a decrease of 34 cases as compared with the year 1916. In the Maternity Hospital there were 309 confinements. In the Victoria Hospital for Women and Children 147 patients were treated. At Kennedy Town Infectious Diseases Hospital 31 cases of small-pox were admitted. In the Tung Wa Hospital only Chinese are treated. Various other services not appertaining to a hospital are performed by the institution, such as the free burial of the poor, the repatriation of destitutes, and the organisation of charitable relief in emergencies. Chinese as well as European methods of treatment are employed in accordance with the wishes expressed by the patients or their friends. About half the number are now treated by Western methods. There are 323 beds in the buildings and 5352 patients were accommodated during 1917. The Tung Wa also maintain a branch hospital for small-pox cases (Chinese only) at Kennedy Town; it contains 58 beds and 146 cases were treated. The Alice Memorial and Affiliated Hospitals are managed and controlled by the missionaries resident in Hong-Kong, agents of the London Missionary Society, and consist of the Alice Memorial Hospital, the Nethersole Hospital, the Alice Memorial Maternity Hospital, and the Ho Miu Ling hospital. The in-patients in 1917 totalled 1670; the number of labours in the Maternity Hospital was 590. The new Kwong Wa Hospital for Chinese in the Kowloon Peninsula contains 70 beds and 2388 patients were accommodated during 1917.

THE "LIMPET" SYSTEM OF ELECTRODES.

OUR attention has been called to an invention which enables medical men to make their own electrodes in any required shape and, by means of a non-absorbent aseptic fastening, to apply and fix the electrode at any desired spot on the patient. The complete outfit consists of nine rubber belts of different sizes and two terminal attachments for placing beneath the belt after the electrode, which is cut by the operator from non-oxidisable plastic metal, has been fixed in position. The chief advantage claimed for the system is that the terminal does not break away by use and so render the whole electrode valueless. The manufacturers are the Medical Supply Association, 167–185, Gray's Inn-road, W.C.1.

DISABLED OFFICERS' HOME AND CLUB; SEASIDE BRANCH AT FRINTON.

THE Home and Club founded by Miss Phyllis Holman, and privately endowed, has now been established on permanent lines. Residence is provided for 25 discharged officers with 100 per cent. disability who require medical or nursing attention or the services of orderlies, and who are unable to take up remunerative work. Contribution of 1–2 guineas a week is made towards the running expenses, according to individual circumstances. The remaining two-thirds of the cost is covered by private endowment and by an agreement with the Pensions Ministry in regard to individual cases requiring continual treatment. Dr. F. E. Easton is honorary medical officer, and Sir George Makins, Sir David Ferrier, Professor F. W. Mott, F.R.S., Mr. J. P. Lockhart-Mummery, and Dr. R. Riddoch are acting as consultants.

Vacancies.

For further information refer to the advertisement columns.

Aberystwyth Infirmary & Cardiganshire General Hospital.—H.S. £200.
Alton, Hants, Lord Mayor Treloar Cripples' Hosp.—Asst. Res. M.O. £200.
Brighton, Royal Sussex County Hospital.—Asst. Path. £200.
Buxton, Derbyshire, Devonshire Hospital.—Asst. H.S. £120.
Glamorgan County Asylum, Bridgend.—Temp. Asst. M.O. £6 6s. per wk.
Hospital for Consumption and Diseases of the Chest, Brompton.—H.P. 30 guineas.
Hospital for Sick Children, Great Ormond-street, London.—H.S. £100.
Leicester Borough Mental Hospital, Humberstone.—Locum Tenens M.O. 7 gs. per week.
London County Mental Hospitals.—Temp Asst. M.O.'s. 7 gs. per week.
Manchester and Salford Lock Hospital.—Female Clin. Asst.
Montgomeryshire Education Committee.—School Dentist. £400.
National Hospital for Diseases of the Heart.—Non-Res. M.O.
Plymouth, South Devon and East Cornwall Hospital.—M.O. £350. Also H.S. £250.
Prison Commission.—Two Female Doctors. 7 gs. per week.
Putney Hospital, Lower Common, S.W.—Res. M.O. £150.
Royal Free Hospital, Gray's Inn-road, W.C.—Female Asst. Anæs: £50.
Salisbury General Infirmary.—Asst. H.S. £150.
Southampton Free Eye Hospital.—Asst. Oph. Surg. £100.
Whitehaven and West Cumberland Infirmary.—Res. H.S. £150 to £180.
Winchester, Royal Hampshire County Hospital.—Jun. Res. M.O. £250.

Births, Marriages, and Deaths.

BIRTHS.

HALL.—On Dec. 15th, at a nursing home, to Margaret, wife of Major G. Hall, C.M.G., R.A.M.C.(T.), 9, Ellison Place, Newcastle-on-Tyne—a daughter.

UNDERWOOD.—On Dec. 10th, at Welford, Rugby, the wife of Dr. F. L. Underwood, of a son.

DEATHS

HAMILTON.—On Dec. 20th, after long illness, Thomas Hamilton, M.B., F.R.C.S.E.

JOHNS.—On Dec. 16th, at Leeds-road, Harrogate, Dr. Frederick Arthur Johns, M.B. Lond., aged 45 years.

LANGFORD.—On Dec. 15th, at the 84th Military Hospital, Dar-es-Salaam, from influenza, Surgeon Lieutenant-Commander Martyn Henry Langford, D.S.O., R.N., H.M.S. *Challenger*, aged 34.

ROWLAND.—Killed in action in France, on Nov. 1st, Second Lieutenant John W. B. Rowland, Royal Field Artillery, D 175 Army Brigade, British Expeditionary Force. France, only son of Dr. E. D. Rowland, I.S.O., Colonial Medical Service, British Guiana, Georgetown, Demerara, aged 19 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Communications, Letters, &c., to the Editor have been received from—

A.—Col. J. G. Adami, A.D.M.S.; Mr. R. J. Albery, Lond.; Surg.-Lieut. D. K. Adams, R.N.; Dr. C. J. H. Aitken; Mr. E. A. Armstrong, Lond.

B.—Dr. T. H. Brown, Lond.; Board of Agriculture and Fisheries, Lond.; Dr. W. Langdon Brown, Lond.; Prof. W. A. Bone, Lond.; Sir James Barr, Liverpool; Dr. G. M. Baskett, Caradon; Surg.-Capt. P. W. Bassett-Smith, C.B., C.M.G., R.N.; Capt. P. Bahr, R.A.M.C.; Mrs. C. Brereton, Lond.
